NEW SERIES. VOLUME XXXV

JANUARY-JUNE, 1912

NEW YORK
THE SCIENCE PRESS
1912

THE NEW ERA PRINTING COMPANY,
41 NORTH QUEEN STREET,
LANCASTER, PA.

CONTENTS AND INDEX.

NEW SERIES. VOL. XXXV.—JANUARY TO JUNE, 1912.

The Names of Contributors are printed in Small Capitals.

- A.**, C., Meteorology, W. I. MILHAM, 743
A., J. A., Birds of Colorado, W. L. SCLATER, 828
Abbot, C. G., The Sun, C. L. POOR, 630
Abbott, C. G., Osprey, F. H. HERRICK, 780
Abel, O., Paleobiologie, W. D. MATTHEW, 341
Acoustics, F. R. WATSON, 833
Aerial Engineering, A. LAWRENCE ROTCH, 41
Agriculture in Schools, L. S. HAWKINS, 927
Agronomist, The American, H. J. WHEELER, 81
d'Albe, E. E. F., Contemporary Chemistry, 697
Albino Race of Deermouse, W. E. CASTLE, 346
Aldrich, J. M., Water Power, 338
ALLEN, J. A., Wild Sheep in Upper Yukon, C. Sheldon, 105; Birds of N. A., R. Ridgway, 499
American Association for the Advancement of Science, Washington Meeting, J. Zeleny, 1; Address of Vice-president of Sect. D, 41; of Sect. H, 46; of Sect. I, 129; Sect. Zool., M. A. BIGELOW, 191; Sect. Math. and Astron., G. A. MILLER, 220; Sect. Physics, E. D. COLE, 510; Sect. of Eng. and Mech. Sci., G. W. BISSELL, 547; Sect. Anthropology, G. G. MACCURDY, 665; Sect. Botany, 909; J. F. CROWELL, 104; C. H. HERTY, 668; Philosophical Soc., 99, 755; A. W. GOODSPEED, 785; Year Book, J. RITCHIE, Jr., 869
Antarctic Explorations, 447
Anthropological Soc. of Washington, T. MICHELSON, 355, 908, 1002; Congress, G. G. MACCURDY, 980
Anthropology at the Washington Meeting, G. G. MACCURDY, 665
Argentine Observatory, C. D. PERRINE, 980
ARKELL, T. E., and C. B. DAVENPORT, Horns in Sheep, 375, 927
Assortative Conjugation, J. A. HARRIS, 740
Astronomical and Astrophys. Soc., R. H. COUTISS, 703
ATKINSON, G. F., R. SHORE, Calceolaria, 280
AUER, J., Digestion, W. B. CANNON, 693
Bacteriologists, Amer., Soc., C. E. MARSHALL, 222
Banks, C. S., Philippine Silk Culture, L. O. H., 274
BANKS, N., Notes on Entomology, 217; Woodland Idyls, W. S. BLATCHLEY, 748
Baskerville, C., Chemistry, J. E. G., 189, 697
BATHER, F. A., Genotype, 270
BEEDE, J. W., Red Beds of Oklahoma, 348
BENEDICT, F. G., A Fasting Man, 865
BENEDICT, H. M., Meristematic Tissue, 421
BENNER, R. C., The Smoke Problem, 977
BENTON, J. R., A Falling Cat, 104
Benzoic Acid, 577
BERRY, E. W., Paleobotanische Literatur, W. J. Jongmans, 217
BESSEY, C. E., Botanical Notes, 456, 589, 829, 994; Bacteria and Plant Diseases, E. F. SMITH, 659; Botany, J. M. COULTER, C. R. BARNES, H. C. COWLES, 781
BIGELOW, M. A., Sect. Zool. Amer. Assoc., 191
BINGHAM, H., Peruvian Expedition, 756
Biochemical Problems in Bacteriology, F. P. GORHAM, 357
Biological Survey, F. RAMALEY, 60; Chemists, Amer. Soc., A. N. RICHARDS, 195; Soc. of Wash., M. W. LYON, JR., 971
Biology, Sec., N. Y. Acad., W. K. GREGORY, 595; Experimental, M. C. HALL, 755
BIRD, K. M., Philos. Soc. of Wash., 908
Birds, Terms used to denote Abundance, J. D. KUSER, 930
BISSELL, G. W., Sect. of Mech. Sci. and Engineering, Amer. Assoc., 547
Blatchley, W. S., Woodland Idyls, N. BANKS, 748
Blücher, H., Industrial Chemistry, A. S. CUSHMAN, 905
Boas, Radosavljevich's Critique of, R. H. LOWIE, 537
BOLTWOOD, B. B., Radio-elements, F. SODDY, 542
Botanical Soc. of Amer., G. T. MOORE, 147; Soc. of Washington, W. W. STOCKBERGER, 199, 436, 716, 1004; Notes, C. E. BESSEY, 456, 589, 829, 994
BOWLES, O., Crystallographic Tables, 576
BOWMAN, J. N., Pacific Assoc. of Sci. Soc., 836
BRIGHAM, A. P., Assoc. of Amer. Geographers, 222
Brigham, A. P., Commercial Geography, W. M. GREGORY, 374
British Insurance Act, 62; Association, 686
BRITTON, W. E., Insect Pests, E. D. SANDERSON, 929
Brown, G., Melanesians, W. HOUGH, 454
Brush, George Jarvis, W. E. FORD, 409
Bryan, G. H., Aviation, W. J. HUMPHREYS, 543
BURTON, T. E., Cause of High Prices, 129
Butler, Samuel, V. L. KELLOGG, 769
BUTMAN, C. A., Physical Lab. Instruction, 61
C., H. W., Pharmaceutical Bacteria, A. SCHNEIDER, 868
CAJORI, F., Hindu-Arabic Numerals, D. E. SMITH and L. C. KARPINSKI, 501
Calceolaria, Spurred Flowers, G. F. ATKINSON, R. SHORE, 280
Calman, W. T., Crustacea, F. H. HERRICK, 187
Campbell, D. H., The Eusporangiate, E. C. JEFFREY, 866
Cancer, Human and Crown Gall, E. F. SMITH, 161; Research, W. B. C., 979
CANNON, W. A., Journey across the Sahara, 455; Deciduous Rootlets of Desert Plants, 632
Cannon, W. B., Physiology, Y. HENDERSON, 504; Digestion, J. AUER, 693
CARHART, H. S., Benjamin Franklin Thomas, 647
CARLSON, A. J., Physiol. Soc. of Amer., 193
Carnegie Institution, 437; Foundation, 477
Case, E. C., Cotylosauria, S. W. WILLISTON, 779
CASTLE, W. E., Albino Race of Deermouse, 346; Pink-eyed Guinea-pig, 508; Horns in Sheep, 574

- Castle, W. E., Heredity and Breeding, J. P. McM., 624
- Cat, A Falling, J. R. BENTON, 104
- CATELL, J. McK., University Control, 797, 842
- Cerium, B. K. EMERSON, 776
- CHAMBERLIN, T. C., Agriculture, F. H. King, 72
- Chance and the Prepared Mind, R. M. PEARCE, 941
- Chemical, Soc., Amer. C. L. PARSONS, 79, 378, 422; New York Sect., C. M. JOYCE, 595; Analyst, H. P. TALBOT, 397; Engineers, J. C. OLSEN, 475
- Chemistry Teaching, H. C. JONES, 87
- Chestnut-tree Blight, M. MANSON, 269; H. METCALF, J. F. COLLINS, 421; W. G. FARLOW, 717
- China Professorships, 328
- CHRISTIAN, H. A., Examinations in Harvard Medical School, 485
- Chromosomes in Wheat, W. J. SPILLMAN, 104
- Church, A. E., and G. M. Bartlett, Descriptive Geometry, C. J. KEYSE, 304
- CLARK, G. A., Pribilof Fur-seal Herd, 336, 546
- CLARK, H. L., Fossil Holothurians, 274; Echini, R. T. JACKSON, 986
- Clark, Henry James, F. TUCKERMAN, 725
- CLARK, W. B., Cretaceous Deposits, F. H. KNOWLTON, 746
- Clarke, H. T., Organic Analysis, J. E. GILPIN, 696
- Clouds over Fires, W. N. LACY, 215
- Cockayne, L., Dune-areas of N. Z., R. J. POOL, 699
- COCKERELL, T. D. A., Genotype, 304; Mollusca of Patagonia, H. A. PILSBRY, 544; Biology of the Seasons, J. A. THOMSON, 967; Natural History of Selborne, G. White, 967
- COLE, A. D., Sect. Physics, Amer. Assoc., 510
- COLE, F. N., Amer. Math. Soc., 119, 594
- Color Variations in House Mice, L. R. DICE, 834
- Complimentary Copies of Books, V. KARAPETOFF, 452

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE THE WASHINGTON MEETING

THE sixty-third meeting of the American Association for the Advancement of Science was held at Washington, D. C., December 27 to December 30, 1911, under the presidency of Dr. Charles E. Bessey, of the University of Nebraska. The meeting was the most successful in the history of the association, both from the point of attendance and from the enthusiasm shown. Beautiful weather prevailed throughout and the people of Washington, including the many scientific men connected with the various governmental bureaus, did everything in their power to make the stay of the visitors pleasant and profitable. The total registration of members of the association was 1,306, whereas the largest previous registration was that at the third Boston meeting, when the total was 1,140. A conservative estimate of the actual number of members of the association present in Washington would place the number at 1,800 and there were doubtless as many as a thousand more present who are members of affiliated societies and not members of the association itself. The following is a list of affiliated and other scientific societies which met in Washington at the same time.

Astronomical and Astrophysical Society of America.
American Physical Society.
American Society of Biological Chemists.
American Chemical Society.
Association of American Geographers.

Geological Society of America.
Paleontological Society of America.
American Association of Economic Entomologists.
Entomological Society of America.
American Breeders' Association.

American Psychological Association.
 Southern Society for Philosophy and Psychology.
 Botanical Society of America.
 American Fern Society.
 Society for Horticultural Science.
 American Microscopical Society.
 American Nature-Study Society.
 American Phytopathological Society.
 Sullivant Moss Society.
 American Anthropological Association.
 American Folk-Lore Society.
 American Civic Alliance.
 American Economic Association.
 American Association for Labor Legislation.
 American Sociological Society.
 American Statistical Association.
 American Home Economic Association.
 American Physiological Association.
 Society of American Bacteriologists.
 American Federation of Teachers of the Mathematical and Natural Sciences.
 Sigma Xi.

The opening reception to members of the association and affiliated and visiting societies was given at the new National Museum from 8 to 9 P. M. of December 27. At the close of the reception, the association held its first general meeting in the assembly hall of the new National Museum. The meeting was called to order by the retiring president, Dr. A. A. Michelson, who introduced the president-elect, Dr. Charles E. Bessey, who in turn introduced the President of the United States, William H. Taft, who delivered the following address of welcome:

I had a Christmas present a day or two ago. It was a new Encyclopædia Britannica. On the first page of it—I suppose that was the reason why I got it—there was a dedication to King George V. and William Howard Taft, president of the United States. Standing as I do in the presence of this live encyclopedia of all knowledge, I have the same feeling of awe now that I had when I saw that name before all the knowledge of the world. At first I thought somebody else ought to speak before me, but I am glad to come first, because as a welcomer it is not necessary for me to advance a single scientific proposition. I am here only as the Mayor of Washington to advise you that you have the freedom of the

city and that it is a beautiful city which you can not stay too long in. Indeed the longer you stay, the longer you want to stay.

We have centers of science here. We have the Carnegie Foundation for Scientific Research, and one of these days I am going to read the things that come from that research, when I have plenty of time. Then, we have a number of bureaus that I presume would be called bureaus of applied science. I don't refer to the science of government—that is altogether too inexact a science for an assembly like this—but I mean there are certain bureaus connected with this government that I hope present matters of interest to so learned and scientific a body as this. There are some of them that I would like to get my hands on and change, but there are limitations upon the power of the president of the United States and he can not do everything he would like. If I could change the Naval Observatory into a bureau, with a scientific professor at the head of it, I would do it to-morrow, but there are conservative gentlemen connected with the coordinate branches of the government that prevent.

Then, we have the Geological Survey and the Bureau of Chemistry and the Bureau of Entomology and the Bureau of Standards. I have no doubt there is a much longer list, which if I had only committed it to memory, I would give here for your studious consideration. But it is enough of a congeries of scientific nerves to justify a meeting of all the scientific bodies of the country here, and I hope that as the government goes on and as congress becomes more liberal, those centers of scientific research, as many of them ought to be, will be improved so as to commend them to those of you who have theories as to what they ought to be under the auspices and with the necessary money which the United States can devote, if it will, to useful scientific research.

There is only one other remark which I wish to make to-night. In thinking over what there was between this audience and me, of any possible common knowledge, it occurred to me it was some experience in the exercise of the judicial faculty—that is in your lives and in your branches of study and action, the search for truth without regard to the result you reach. That is what makes the administration of justice, what makes the work upon the bench so delightful—the absolute indifference to a result, with the weighing of the reasons pro and con and the final solution in accordance with eternal justice. The scientific man in his search for the truth of nature, in

which he could wrest a rule from nature—a law—and in which he studies each individual instance to find that law, or, if he thinks he has found it, to make the instance square with the law, exercises the judicial faculty in a different branch, but with the same necessity for absolute adherence to truth in order that a useful result may be reached—no forcing of a theory, no construction of individual instances in order to make a theory, if those instances really don't fit into it; and if I know the weakness of the scientist or the temptation of a scientist, it is in reference to just such cases as that. Just as the judge upon the bench, with a weakness for deciding a case in advance, because he has heard one or two things in it, and then tries to square everything else that comes along to his original theory, so, too, with you. I have no doubt that what you have to struggle against is too quick recognition of something that leads you to discover a law. Subsequent study changes your mind about it and then you have to go back and build up a new theory or law, slowly, deliberately, but with strict adherence to truth and a desire to find the truth until you finally conquer and reach a conclusion that will bear the test of every instance.

Dr. Walcott, Secretary of the Smithsonian Institution, who was to have given the second address of welcome, was absent through illness.

President Bessey responded to the address of welcome, as follows:

Mr. President:

The members of the American Association for the Advancement of Science feel it to be a great honor to be welcomed to the capital of the country by its foremost citizen, the president of the United States.

In theory at least scientific men are like the men who frequent this city. They are here for a particular purpose. They work for the good of the community. They are not working for their own advancement. They are servants of the people. In all these things we are like the men who occupy legislative, judicial or executive positions in this capital city.

But, Mr. President, you will permit me to suggest, without unseemly egotism, that in the coming of this body of scientific men to the capital, we represent more than an invasion of an equal number of congressmen, judges and executive officers. If I may be allowed to say it, the latter represent

present problems and needs, and deal only with the things of immediate importance. They are time servers often, or may be mostly in the better sense, but still servers of the present time. And no one will question the usefulness of the man who honestly and conscientiously serves his day and generation—his time.

To the man of science the past, the present, the future, are spread out as the great panorama of nature on which are sketched the successive pictures of an eternity of change and evolution, whose beginning we do not know, and of whose end we have no conception. The politician works wholly in the present and for the present: the scientist's work carries him back through eons of duration to the dawn of eternity, and forward through countless millenniums to a possible twilight time of the universe.

I am not saying that all scientists live in the eternities in this high fashion, nor am I denying that there are great minded statesmen who live in a present which is illumined by the past, and beckoned by the future. No, I would not dare to claim so much for all who enroll in the ranks of science, and certainly we know of some men in public life whose breadth of view on the political questions of the day entitles them to the distinguished name of statesmen.

So I stand here representing a body of men, in some respects like those who are visibly engaged in conducting the government of the country, but in other respects constituting a very different body, and it is on their behalf that I thank you sincerely for the cordial welcome you have extended to us.

But while I speak I am reminded that in these later years you have taken into the service of the government many hundreds of trained scientific men, and that these men by their labors are helping you to solve some of the most difficult problems that the government has had to face. With these men we who assemble here to-day have close ties and cordial sympathies. We remember that although in government service they are still scientific men, and that the problems you have placed before them are scientific problems. And we are anxious, Mr. President, that these brothers of ours shall have full opportunity for doing well the work put before them. We are glad that by the establishment of an enlightened system of laws controlling the civil service this body of scientists has been lifted out of the reach of petty personal politics. That has made it possible for

the government to secure the services of so many men of the highest scientific attainments. It now remains for you, Mr. President, as the executive head over all the scientific bureaus to see that the proper atmosphere is maintained in every bureau, and in every division where scientific men work. It has been hinted sometimes that with all that has been done so well to keep the outside politician away from the scientist's laboratory, we have not wholly succeeded in keeping the inside politician from creating an atmosphere quite inimical to scientific work. For it must be remembered that scientific work is not all a digging out of facts as is so often supposed, but that the best of it calls for comparison, and reflection, and the careful drawing of conclusions, and this takes much time, and mental leisure, and a freedom from petty irritations.

If the men who have to solve the scientific problems of the government are to discharge their duties with the highest efficiency, they must have good appliances in the way of laboratories, experimental stations, apparatus, reference libraries and such other material necessities as pertain to the particular work they have in hand, but more than these, far more I may say, is the necessity for a congenial and sympathetic environment. And rumor has it that this helpful environment is not always present in the splendidly equipped divisions, where it may be that the expert scientist is hampered and distracted by the necessity of making preliminary plans, and preliminary projects, and final plans and final projects, and reports of progress, and preliminary reports, and final reports, and supplementary reports, to officials who neither understand the nature of the problems nor the scientific methods of their study.

We shall agree that these things ought not to be, and I am assured by the interest you have shown in the scientific work of the country at large, and especially by what you have done here in the capital that you will gladly help to free the government scientists from such trammels as may have sometimes hedged them in. In these days when we are applying "scientific management" to business and the industries certainly we ought to have a scientific management of our bureaus of science.

Mr. President, I regard it as a great honor to have had the privilege of responding to the welcome extended to this Association, and doubly so when that welcome has been given by you, whom we all delight to honor, as the president of this good country of ours.

The annual address was then delivered by the retiring president Dr. A. A. Michelson, on "Recent Progress in Spectroscopic Methods," after which the meeting was adjourned.

The addresses by retiring vice-presidents of sections were made as follows:

WEDNESDAY AFTERNOON

Vice-president Frankforter before the Section of Chemistry. Title: The Resins and their Chemical Relations to the Terpenes.

Vice-president Harper before the Section of Botany. Title: Some Current Conceptions of the Germ Plasm.

THURSDAY AFTERNOON

Vice-president Rosa before the Section of Physics. Title: Work of the Electrical Division of the Bureau of Standards.

Vice-president Rotch before the Section of Mechanical Science and Engineering. Title: Aerial Engineering.

Vice-president Hill before the Section of Education. Title: The Teaching of General Courses in Science.

FRIDAY MORNING

Vice-president Moore before the Section of Mathematics and Astronomy. Title: On the Foundation of the Theory of Linear Integral Equations.

FRIDAY AFTERNOON

Vice-president Dixon before the Section of Anthropology and Psychology. Title: The Independence of the Culture of the American Indian.

Vice-president Novy before the Section of Physiology and Experimental Medicine. Title: Carriers of Disease.

Vice-president Burton before the Section of Social and Economic Science. Title: The Cause of High Prices.

Among other addresses which were given and meetings for general discussion which were held, the following may be mentioned:

On Thursday morning, there was a symposium on "The Ether" before the American Physical Society, which was led by Professor A. A. Michelson, who was followed by Professor A. G. Webster and others.

Dr. H. B. Talbot, chairman of the Division of Physical and Inorganic Chemistry, delivered an address on Wednesday afternoon, on the "Privileges and Responsibilities of the Chemical Analyst."

On Thursday evening, the president of the American Chemical Society, Dr. Alexander Smith, addressed the society on the subject, "An Early Physical Chemist." The address was followed by a lecture by Frank B. Kenrick and H. E. Howe, on "Lantern Experiments on Reactions in Heterogeneous Systems."

A symposium on "Drug Assay" was held on Friday morning by the Division of Pharmaceutical Chemistry, and one on "Mineral Wastes and Conservations" was held by the Division of Industrial Chemists and Chemical Engineers.

President R. S. Tarr, of the Association of American Geographers, gave his presidential address on Friday morning, on "The Glaciers and Glaciation of Alaska."

The Paleontological Society of America held a symposium Friday morning, on "Ten Years Progress in Vertebrate Paleontology."

A symposium on "Instinct and Intelligence" was held on Wednesday morning by the American Psychological Association.

The subject of the address of President Franz of the Southern Society for Philosophy and Psychology, given on Thursday afternoon, was "New Phrenology" and that of President Seashore, of the American Psychological Association, given on Thursday evening, was "The Measure of a Singer."

Professor J. H. Comstock addressed the Entomological Society of America on Wednesday evening on "Some Biological Features of Spiders."

The Section of Botany held a symposium on "Soils" on Wednesday afternoon, and the Botanical Society of America held a symposium on Thursday afternoon on

"Modern Aspects of Paleobotany" after the retiring president, Dr. E. F. Smith, had delivered his presidential address on "Some Aspects of the Relationship of the Crown Gall Disease to Human Cancer."

Dr. H. M. Beldon gave his presidential address, on "Folk Poetry in America," on Thursday morning, before a joint session of Section H and the American Folk-Lore Society. In the afternoon, the joint session was in charge of the American Anthropological Association and a symposium was held on "Environment and Culture."

Presidential addresses by Dr. F. H. Giddings, president of the American Sociological Society, on the "Quality of Civilization" and by Dr. H. W. Farnum, president of the American Economic Association, on "The Economic Utilization of History," were given before a joint meeting of the two societies, on Wednesday evening.

On Friday afternoon at a joint meeting of Section K with the American Physiological Society and the Society of American Bacteriologists a symposium was held on "Acapina and Shock."

The council of the American Association met daily and the following are the chief items of business transacted:

Eighty-seven new members were elected into the association, and the following were elected fellows of the association: Frank H. Bailey, Fred Asa Barnes, John Fritz, A. A. Hammarslog, Truman Michelson, F. Paul Anderson, Gardner Chace Anthony, Henry Sturgis Drinker, Louis Doremus Huntoon, William Christian Hood, Clement Ross Jones, John Price Jackson, James W. Lawrence, Edwin Hoyt Lockwood, Chas. E. Suche, Francis C. Shenehon, Frederick W. Sperr, James T. Beard, Wm. J. Sharwood, Lula Pace, Pliny E. Goddard, George Byron Gordon, Guy M. Whipple, Milo B. Hillegas, Frederick E. Farrington, Harold

A. Wilson, Frank Wenner, F. C. Brown, E. A. Harrington, W. J. Fisher.

The report of the treasurer for 1910 was presented by the permanent secretary and was accepted and ordered placed on file. The financial report of the permanent secretary was presented, accepted and ordered published.

Dr. H. E. Summers was elected secretary *pro tem* of the council.

The following resolutions were adopted:

1. WHEREAS, the will of the late Jane M. Smith, of Pittsburgh, Pa., a former life member of the American Association for the Advancement of Science, contains the following bequest, namely:

"Seventeenth: I give and bequeath to the National Geographic Society of Washington, D. C., the sum of five thousand dollars (\$5,000); to the American Forestry Association of Washington, D. C., the sum of five thousand dollars (\$5,000); and to the American Association for the Advancement of Science of Washington, D. C., the sum of five thousand dollars (\$5,000). I hereby direct that each of said sums be invested and the net income thereof be used for the purpose of creating life members of said three organizations in cases where worthy and competent persons are not able to pay for such memberships."

Be it therefore *Resolved*, That the permanent secretary of the association be and hereby is authorized to accept from the executors of Jane M. Smith, deceased, the legacy of five thousand dollars (\$5,000) bequeathed by her to the American Association for the Advancement of Science as a fund whose income may be used in the payment of life-membership commutations in the association.

Resolved, That this fund be designated as the Jane M. Smith Fund of the American Association for the Advancement of Science.

Resolved, That said sum of five thousand dollars (\$5,000) or any instalments thereof as they may be received, be turned over to the treasurer of the association for investment in such manner as the council of the association may direct.

Resolved, That the application of the income of the Jane M. Smith Fund in conformity with the wishes of the testatrix be determined by the council of the association after reference to and recommendations from the committee on policy.

2. WHEREAS, more than fifty per cent. of the

injurious insects and plant diseases of first-class importance in the United States have been imported accidentally or in the course of commerce from other countries; and

WHEREAS, the United States of America is the only country among the great nations of the world which has no national quarantine or inspection service looking towards the prevention of such introductions:

Therefore be it *Resolved*, That in the opinion of the American Association for the Advancement of Science the passage of a national quarantine and inspection law directed against the introduction and establishment of injurious insects and plant diseases from other parts of the world is a great desideratum at the present time.

The permanent secretary was directed to transmit copies of this resolution to the president of the United States, the president of the senate, the speaker of the house and the chairman of the committee on agriculture of the house of representatives.

3. *Resolved*, That the permanent secretary be instructed to present for nomination to fellowship the names of those members who are members of affiliated societies, which have already been designated as having qualifications for membership equivalent to fellowship in the association.

4. *Resolved*, That the council of the American Association for the Advancement of Science approves the creation of a Bureau of Astronomy with a scientific chief, which shall have charge of the Naval Observatory and of the Nautical Almanac, and respectfully requests that every endeavor be made to put into operation this plan in the interests of astronomy in the United States.

The permanent secretary is requested to forward a copy of this resolution to the president of the United States, to the president of the senate and to the speaker of the house of representatives.

5. *Resolved*, That Section I be given permission to meet at times and places different from those of the general association, whenever the sectional committee and the committee on policy so agree.

6. *Resolved*, That the treasurer of the association be authorized to invest \$20,000 of the permanent funds of the association in such interest-bearing securities as the committee on policy of the association may approve.

The council instructed the permanent secretary to publish in February or March next a list of officers and members of the

association. The resignations of N. L. Britton and W. H. Welch from the Committee on Policy were accepted and D. T. MacDougal and W. J. Humphreys were appointed to fill the vacancies.

The council authorized an increase in compensation of the present assistant to the permanent secretary from \$100 per month to \$125 per month.

A resolution was adopted recommending that future delegates from the association to international conferences and other delegate bodies be requested to submit brief reports to the council.

A report from Dr. Hutton Webster, delegate to the First Races Contest, was read and ordered filed, and the report of Dr. B. Shimek, delegate to the Third National Conservation Congress, was presented and placed on file.

The council resolved that the American Association for the Advancement of Science reaffirms its approval of the establishment of a National Department of Public Health.

Senator Theodore E. Burton, Dr. Wm. Trelease and Dr. Henry B. Ward were elected to fill vacancies in the council.

The following grants were allowed for the ensuing year:

To the Concilium Bibliographicum \$200
To Mr. Frank C. Gates, A.B., for an investigation of the relation of transpiration to plant structure in bog plants, in collaboration with Professor T. C. Newcombe \$100

The following amendments to the constitution were read as a formal notification in order that they may be acted upon next year under the provisions of the constitution:

Article 31. Substitute for existing article the following:

"The permanent secretary shall publish from time to time a list of officers and members of the association together with such other matter as the council may direct.

Article 3. In closing line omit the word "annual."

Article 6. Omit final sentence.

Article 10. Omit "in the annual volume of Proceedings."

Same article, omit "to the printing and distribution of the annual volume of Proceedings and all other."

Article 22. After "Education" add

"M, Agriculture," or

"M, Agriculture and Forestry," or

"M, Forestry,"

and

"And the council shall have power to create additional sections from time to time when deemed desirable."

Article 22. Lines 4 and 5, change from "H, Anthropology and Psychology" to "H, Anthropology."

Article 22. Abolish Section I.

At a meeting of the general committee held Friday evening, December 29, it was resolved to hold the next meeting at Cleveland, Ohio, the meeting to begin on the Monday of the week in which January first, 1913, falls. It was further resolved to recommend to the next general committee that the meeting for 1913 be held in Atlanta, Georgia. It was further resolved that the committee looks with favor on the plan of holding a summer meeting on the Pacific coast in 1915.

The following officers were elected for the coming year:

President—Dr. Edward C. Pickering, director of the Harvard Astronomical Observatory.

Vice-presidents:

Sec. A—E. B. Van Vleck, University of Wisconsin.

Sec. B—Arthur Gordon Webster, Clark University.

Sec. C—W. Lash Miller, Toronto.

Sec. D—J. A. Holmes, Washington, D. C.

Sec. E—James E. Todd, University of Kansas.

Sec. F—William A. Leacy, Northwestern University.

Sec. G—D. S. Johnson, Johns Hopkins University.

Sec. H—J. Walter Fewkes, Washington, D. C.

Sec. I—John Hays Hammond, New York.

Sec. K—J. J. McCleod, Cleveland, Ohio.

Sec. L—J. McKeen Cattell, Columbia University.

Secretaries of Sections:

Sec. B—W. J. Humphreys, Mount Weather, Va.

Sec. E—Geo. F. Kay, University of Iowa.

Sec. K—Waldemar Koch, Chicago University.

General Secretary—H. E. Summers, Iowa State College.

Secretary of the Council—H. W. Springsteen, Western Reserve University.

JOHN ZELENY,
General Secretary

**THE WORK OF THE ELECTRICAL DIVISION
OF THE BUREAU OF STANDARDS¹**

1. INTRODUCTION

THE Bureau of Standards has grown considerably, both in equipment and personnel, since its inception in 1901. The original staff of fourteen has increased to nearly three hundred, and the material equipment has been augmented in a similar ratio. Its functions also have developed, although authority for all its manifold activities is contained in the brief act of Congress of March 3, 1901, which established the Bureau, and its growth has been closely along the lines laid down by the director in his first announcements of the policy of the new bureau.

The name Bureau of Standards does not signify to the average person the wide scope of the work of the bureau, which is really a national physical, chemical and engineering laboratory. In Germany there are three similar national institutions, and the establishment of a fourth has been proposed; these four combined would cover the field occupied in this country by the Bureau of Standards. The German institutions referred to are the *Physikalisch-Technische Reichsanstalt*, for physics; the *Normal Eichungs-Kommis-*

sion, for weights and measures, and the *Material Prüfungs Amt*, for engineering and the testing of materials. In addition to these three institutions, which have been in active operation for many years, a royal chemical institute for chemistry has been for some time under consideration. In England the National Physical Laboratory occupies a field more nearly like that of the Bureau of Standards, but the Board of Trade divides with it some of these functions.

The work of the Bureau of Standards is distributed among seven divisions, as follows:

- I. Electricity and photometry.
- II. Weights and measures.
- III. Heat and thermometry.
- IV. Optics.
- V. Chemistry.
- VI. and VII. Engineering and the testing of materials.

Thus, it will be seen that the work of Divisions I., III. and IV. correspond to that of the *Reichsanstalt* of Germany, and the remaining four divisions to the other three German institutions mentioned above.

The work of the bureau may be broadly divided into two parts, research and testing, although much time is devoted to the preparation of specifications, the standardization of practise and the diffusion of information that does not fall under either of these heads. To undertake to describe the work of research, testing and standardization carried on in all the divisions of the bureau would be a task requiring more time than is at present available. I shall, therefore, limit myself to the work of Division I., and if I succeed in bringing to your minds a full appreciation of the character and importance of the work we are trying to do in electricity, magnetism and photometry, you may take this when

¹ Address of the vice-president and chairman of Section B, Washington, 1911.

multiplied by six as standing for the work of the bureau as a whole.

2. SCIENTIFIC INVESTIGATIONS

The scientific researches which have been carried out in the electrical division, the results of which are contained in more than 100 papers published in the *Bulletin* of the bureau, may be grouped under the following five heads.

(a) *Theory of Electrical Measurements and of Absolute Instruments.*—One of the first things that demanded attention when the bureau was established was the fixing and maintaining of the standards for electrical measurements, and the choice and development of methods of measurement. This has involved a thorough study of the theory of electrical measurements, and of the theory of the absolute instruments which are employed in the various kinds of absolute electrical measurements. Such studies naturally led to new methods and to the improvement of existing methods, and to a better knowledge of the theory of electrical measurements and of electrical instruments. The *Bulletin* contains twenty-seven papers under this head, including such subjects as the calculation of self and mutual inductance of the various kinds of coils used in the absolute instruments employed in the measurement of resistance and current in C.G.S. units, and in many other kinds of measuring instruments; the theory of different kinds of electro-dynamometers, and of a new method for the absolute measurement of resistance; theory of coupled circuits and other problems in wireless telegraphy, and the preparation of a complete list of formulæ for use in calculating inductances of almost every kind of electric circuit.

(b) *Methods of Electrical Measurement.*—In the work of electrical testing

and research much attention was given to improving methods of measurement, and the *Bulletin* contains thirty-three papers on this subject, including the absolute measurement of inductance and of capacity, the measurement of inductance in terms of capacity by means of alternating currents, wattmeter methods of measuring power, the influence of wave form upon electrical instruments and upon hysteresis losses in iron, the measurement of energy losses in dielectrics, and in iron, a standard method of demagnetizing iron in measurements of magnetic induction, methods of testing transformer iron, measurement of the ratio of transformation and of phase relations in current and potential transformers, quantitative measurements in radio-telegraphic circuits and experiments with high frequency circuits and various papers on methods of measurement in photometry.

(c) *Experimental Researches upon Concrete Electrical Standards.*—The results of absolute electrical measurements are preserved by means of concrete electrical standards, and the practical units of electrical measurements as defined and agreed to by international electrical congresses are expressed in terms of concrete electrical standards, and not in terms of the C.G.S. system. The accuracy attainable in absolute measurements and the definiteness of legal values are both limited by the constancy and reproducibility of the concrete standards by means of which they are expressed and preserved. The principal concrete standards are (1) the *mercury column*, the resistance of which defines the international ohm, and the *wire standards* to which values are assigned in terms of the mercury ohms; (2) the *silver voltameter* which defines the international ampere; and (3) the *Weston normal cell*, the concrete standard employed for the measurement of

electromotive forces, and the value of which is fixed in terms of the international ohm and the international ampere. These concrete standards were defined by the Chicago Electrical Congress of 1893. The principal countries of the world did not, however, adopt the Chicago specifications and numerical values unchanged, so that the international uniformity hoped for was not altogether realized. As the precision of electrical measurements increased and there came a demand for greater accuracy in electrical instruments, the old specifications became inadequate, and the differences in numerical values between different countries became more and more annoying. After attention had been drawn at St. Louis in 1904 to the need of a new international conference for the purpose of securing improved specifications for the concrete electrical standards and uniform numerical values for the same, and after a preliminary conference at Charlottenburg in 1905, in which the program for such an international conference was carefully considered, the conference was called by Great Britain, and met in London in October, 1908. Although considerable attention has been given to the subject of absolute electrical measurements and the preparation of the concrete electrical standards in the fifteen years between 1893 and 1908, it was found at the London Conference impossible to formulate complete specifications for the three primary electrical quantities, and impossible to agree upon a satisfactory value for the Weston normal cell, which latter was adopted at London in place of the Clark cell, as the official standard for expressing the value of the international volt. The discussion at the London Conference brought out clearly the inadequacy of a bulky international conference, sitting for a week or ten days once or twice in a generation, as a tribunal for

settling wisely such technical questions as are involved in the specifications of electrical standards and fixing the values of the standard cells so that it would satisfy Ohm's law. It was recognized that this law could not be repealed or ignored, even by an international conference, and the best that could be done, therefore, was to choose a provisional value for the Weston cell (1.0184 volts at 20°) and to leave to an International Committee on Electrical Units and Standards, established by the London Conference for the purpose, the task of carrying on the investigations, completing the specifications, and finding a new and more precise value of the standard cell. This committee consisted of fifteen members and five associate members, representing eleven different countries, and during the three years that have elapsed since the London Conference it has encouraged investigations in the direction indicated, and has partly accomplished its task. While the committee as a whole has acted in the matter, the experimental work has been done chiefly by the national standardizing laboratories of England, France, Germany and the United States, and in this work the Bureau of Standards has been active.

It might appear that three years is ample time in which to settle all the questions necessary to the satisfactory completion of the work left undone by the London Conference, and so it would be if a reproducibility of one one-hundredth of one per cent. in the standards were deemed sufficient. But when we recall the constancy of the standards of length and mass, and the regularity of the earth as a standard timepiece, we can not be content with our concrete standards of resistance and electromotive force so long as uncertainties exist as great as a thousandth of one per cent. As the demands for greater

precision of measurement increase, the national standardizing laboratory must maintain so high a plane of excellence that those best qualified to judge have the fullest confidence in its fundamental standards and in the accuracy of its work. The endeavor to improve these standards is not merely a matter of doing patiently the same thing over and over again. It means a whole train of investigations, through which an intimate knowledge of the behavior of these standards is obtained, disturbing influences removed or taken account of, impurities in the materials eliminated, and measurements made with what a few years ago would have seemed almost impossible accuracy. The by-products of such researches are often of great value, and become useful in many other directions.

To illustrate, let me refer to the silver voltameter, the concrete standard of electric current. In 1908 it was believed by many that the chemistry of the Rayleigh voltameter was simple, and that the most recently published work upon it had cleared up a mystery of long standing, relative to the disagreement of the Rayleigh and Richards forms of voltameters. Further study at the Bureau of Standards showed complexities due to the presence of filter paper which astonished chemists, and three years of continuous work have not answered all the questions which have arisen as to the effect of traces of organic impurity or of traces of acid or alkali, in the salt, or slight variations in the physical condition of the anode, or the volume and concentration of the electrolyte, or the density of the current, or the influence of dissolved gases. In addition to excellent facilities for purifying materials and making chemical determinations, and an unsurpassed equipment for measuring the current and weighing the deposits, the microscope and ultramicroscope have been

brought into service. And although the outstanding discrepancies are only a few thousandths of one per cent., we have not felt justified in closing the work until the voltameter as a scientific instrument should be as thoroughly understood as possible.

The construction of standard cells has been beset with similar difficulties. The preparation of the materials has been studied with great pains, and hundreds of cells have been set up and carefully studied. To test their portability, they have been carried from country to country and around the world, and even sent through the mails to Europe and elsewhere. To try to determine the source of small differences between different lots of cells, and between different cells of the same lot, one component at a time has been varied, and materials prepared at different times and in different countries have been used side by side. The result has been a considerable improvement in standard cells, so that for most purposes they are satisfactory, but as standards there is still room for improvement.

One reason for desiring more perfect concrete electrical standards is to facilitate absolute measurements. We now know the value of the absolute ampere better than the value of the absolute ohm, but during the next few years the absolute ohm will probably be realized as well as the absolute ampere now is. Our international electrical units are now so well fixed that one can measure electrical power in international watts with great accuracy. With a better knowledge of the absolute ohm, we shall be able also under proper conditions to measure electrical and mechanical power in watts or in absolute units by means of electrical instruments with high precision.

The work at the Bureau of Standards

on the absolute measurement of current, using an improved form of Rayleigh current balance, has been thorough and exhaustive. To obtain a final result reliable to two or three parts in a hundred thousand requires that all possible sources of error as great as a few parts in a million must be examined and taken into account. It would be impossible in this form of current balance to measure directly the dimensions of the coils with the required precision, and hence the constant of the instrument must be determined by electrical means without such direct measurements; and to detect and eliminate unsuspected errors, several sets of fixed coils and several different moving coils were prepared and used interchangeably, giving the equivalent of several balances. This, in fact, did reveal unsuspected sources of error, and although it greatly prolonged the investigation, it gave results far more trustworthy in the end. A similar story could be told of the work at the bureau on mercury ohms, and on the determination of the ratio of the electrical units.

These are some of the researches in connection with electrical standards, which together constitute the third group of investigations in Division I. of the bureau. Some of them are described in papers contained in the *Bulletin*, and some are in press, and some are not yet completed.

(d) *Improvements in Instruments and the Development of New Instruments.*—In addition to new instruments developed and improvements made in existing instruments employed in the absolute measurements mentioned above, many improvements have been made in electrical instruments used for other kinds of electrical measurements.

Some of these improvements have been adopted by American and foreign instrument makers, and some are embodied only

in instruments in our own laboratories. Among these may be mentioned the following:

(1) The Bureau of Standards type of sealed resistance standard, which is used not only for resistances of highest precision in standardizing institutions, but also for precision standards in ordinary use.

(2) The Bureau of Standards chronograph, for measuring and recording with extreme precision the speed of a machine, as, for example, the speed of a dynamo for the purpose of obtaining the frequency of the current generated with highest precision. It is used on the new apparatus for the measurement of absolute resistance at the bureau, and in connection with the absolute measurement of capacity and inductance, and has been adopted by the National Physical Laboratory on the magnificent machine recently erected at Teddington.

(3) The direct reading potentiometers designed for rapid and accurate work in the measurement of current and voltage, which have been of great service in the work of the bureau, and would be more largely used outside if instrument makers had been quicker to appreciate their merits.

(4) The series of electrodynometers for the measurement of alternating current and power, which can be calibrated by direct current and used on alternating. Their range is up to 1,000 amperes, and one recently constructed, but not yet fully installed, will have a range of 5,000 amperes. They are essentially instruments for the testing laboratory, and without them the bureau would have been unable to make many of the tests which have been successfully carried out.

(5) Important improvements have been made in instruments for the accurate comparison of resistance standards and the testing of resistance boxes, potentiometers,

etc. In photometry a number of instruments have been developed or improved, including an automatic recording mechanism, a direct reading scale, a universal rotator, an improved integrating photometer, a direct recorder for life test work, an efficiency meter, etc.

Many other examples of the kind may be cited. In every case, instrument makers and the public have the fullest access to all information concerning new instruments or improvements in old instruments.

(e) *Determining the Properties of Materials.*—The fifth class of scientific investigations concerns the measurement of the properties of materials. Most of the work of this kind is included under the head of testing, the materials tested being in most cases samples of larger lots. But in some cases the work is done to find the average properties of a certain kind of material for the purpose of establishing a standard, or of finding how one property depends upon another. Examples of this kind are the investigations on the mean resistivity and temperature coefficient of resistivity of commercial copper wire. Samples were obtained from many sources, both in America and Europe, and values obtained from measurements made by one of the largest manufacturers, whose instruments and standards had been verified by the bureau.

In this way a mean value was obtained for commercial copper which was made the basis of a new wire table, computed by the bureau at the suggestion of the American Institute of Electrical Engineers, and which they at once adopted in place of their own table. These investigations also brought out a new relation between the temperature coefficient of resistivity and the resistivity itself, so that knowing either of these quantities, the other becomes known.

Another important investigation of this kind recently undertaken is on the relation between the magnetic and mechanical properties of iron and steel, with a view of ascertaining whether it is practicable to test materials for mechanical flaws by magnetic methods. Many investigations on the properties of materials employed in electrical work are needed to answer the hundreds of questions constantly arising, and some of these will soon be undertaken in cooperation with one of the committees of the American Society for the Testing of Materials.

3. ENGINEERING INVESTIGATIONS

In addition to work of the character just described under the head of scientific investigation, laboratory and field work have been conducted on several important practical questions, which may be mentioned under the head of engineering investigations.

One of these had to do with the use of electricity in mines, and the work was undertaken for the purpose of formulating a set of rules suitable for enacting into law, or that could be utilized in revising existing laws, concerning the safe use of electricity for light, power and signals in mines. A careful study of coal mines using electricity, and of the regulations of European and other countries concerning the use of electricity in mines, was made, a great many mining engineers, mine inspectors, mine superintendents and manufacturers of mining machinery were consulted, and the results embodied in a publication on the "Standardization of Electrical Practice in Mines."

Another investigation still in progress has to do with the state and municipal control of the manufacture and sale of illuminating gas. The bureau has been making a thorough study of the methods of testing

illuminating gas for chemical purity, and for its heating and illuminating value. This has involved an investigation of the methods of testing gas and of the instruments employed in such tests. That is, of apparatus used or that may be used in testing for hydrogen sulphide, total sulphur, ammonia, etc.; of gas calorimeters and of gas photometers and flame photometric standards. In connection with this the bureau has made a thorough study of the legal requirements in all the cities and states of the country and of the methods of testing and inspection in use, and has tried to formulate the results of these studies in such a way as to be useful in framing municipal ordinances or state laws on this subject. In this investigation a great deal of field work has been done, and some of the ablest and most experienced gas engineers and city and state inspectors and members of public service commissions have cooperated with the bureau. The results of this investigation, which has already been in progress for more than two years, will be published in two bulletins, one on the specifications of different kinds of illuminating gas and the public regulation of its distribution and sale, and the other on the methods of testing of gas and gas meters. In this work, three of the divisions of the bureau have cooperated.

Another investigation of great engineering importance is that of the effects of stray earth currents (due generally to street railways) upon the corrosion of gas and water pipes and of reinforced concrete structures. Experiments show that under certain circumstances such effects are not only real but serious. The bureau is doing a good deal of field work, as well as laboratory work on this subject, in order to learn the conditions under which the damage is greatest, and how best to

remedy the trouble. The first public report of this work was made recently at the annual meeting of the American Gas Institute, and believing the bureau's work to be of great practical value, the institute voted to appoint a committee to cooperate with the bureau, and expressed the hope that the American Street Railway Association would do the same. Closely associated with the electrolytic corrosion due to stray electric currents is the electrolytic self corrosion, which is under some circumstances very serious and which is often wrongly attributed to railway currents. Electrolytic boiler corrosion, and the corrosion of metal lath used in building, are other examples of the same thing. These are also being investigated, and will be the subjects of published reports.

Another subject of great practical importance that remains to be studied is the life hazard in electric practise, and the proper regulations by states and municipalities for the protection of the public. Much attention is given by the Board of Fire Underwriters to the question of fire hazard, and in protecting buildings from the fire risk much has been done incidentally to reduce the risk to life. But too little attention has been given to the protection of the public from high potential power and lighting circuits, and few cities or states have legislated on the subject. A thorough study of this question, made with the fullest cooperation of the electrical power companies and the manufacturers of insulating materials, would yield results of great practical value, and open the way to municipal and state regulation and inspection.

4. THE TESTING OF INSTRUMENTS AND MATERIALS

Instruments and materials are tested by the bureau for the various departments of

the federal government and for the states and state institutions free of charge. For municipalities and corporations and individuals fees are charged, which in most cases scarcely cover the actual cost of the test, but which are high enough to exclude tests of small importance. In some cases the bureau declines to make tests, as, for example, when it is believed that the proposed test would not settle the question at issue, or where the work would be incommensurate with the value of the result, or where the test is simple and could be done as well elsewhere, and, of course, whenever the facilities or experience of the bureau are not sufficient to warrant attempting the work, or where the work already on hand is too great to permit it. But with these cases excluded, there remains a great variety of tests in all divisions of the bureau, which are being done for the government and the public, and many of these tests are of great practical importance. The fees charged are smaller than they would be if the tests were not generally of value to others besides those who pay for them. Most private tests, indeed, are of public advantage. For example, it is of public concern that manufacturers of electrical instruments have their standards tested at the bureau, as this tends to insure greater accuracy in the instruments sold to the public, without adding appreciably to the cost. That electric lighting companies have their test meters and voltmeters standardized and gas companies have their meter provers and photometric or calorimetric standards tested is a matter of public concern, for it improves the service rendered to the public. If manufacturers of electrical machinery have insulating materials tested for resistance and dielectric strength, and sheet iron and castings tested for magnetic quality, and copper tested for conductiv-

ity, their customers get better machines, and the public better service.

Electrical instruments tested by the bureau include standards of resistance and electromotive force, and precision resistance apparatus of all kinds; condensers and inductances of various kinds used in laboratory measurements and in radiotelegraphy, both commercial and experimental; ammeters, voltmeters, wattmeters, watt-hour meters and many other kinds of measuring instruments, for direct or alternating current; instrument transformers for current and voltage, including those for very heavy currents and high voltages; magnetic instruments; photometers, and various kinds of photometric standards, electric and gas, locomotive headlights, including oil, acetylene and electric; signal lamps, street lamps, etc.

Materials tested include copper, aluminum and other wires used as conductors of electricity; manganin, constantin and other alloys for resistance, thermal electromotive force, etc.; iron and steel and other magnetic or slightly magnetic materials for permeability, hysteresis, coercive force, etc.; sheet steels for iron losses due to alternating magnetizations; insulating materials for instruments and electrical construction; electric lamps for candle power, efficiency and life, and for the quality of the light furnished; oils to be used in standard lamps or as illuminant or for signal purposes, etc.

These tests of instruments and materials are sometimes made for the purpose of seeing whether they conform to the specifications under which they are sold, sometimes for the information of the manufacturer of the given instrument or material, sometimes for the information of an intending purchaser, often for the purpose of re-standardizing the instrument for regular service. A great deal of time is required to keep the equipment employed in testing

in good condition, in order that it may give accurate and trustworthy results, and to check measurements previously made. In most kinds of testing, not half the total cost of the work is due to the time required to make the actual observations and calculations. But that is an inevitable condition, which never can be otherwise. For, if the work is not thoroughly reliable, its value has disappeared.

One of the interesting phases of this testing work is the uniformity which in some cases it maintains throughout the country in the output of different companies and the service rendered by different agencies. Before the bureau began its photometric testing, the standard of candle power varied from ten to twenty per cent. between different companies. The 16 candle-power standard lamps of different manufacturers varied from 14.5 to 17 candles. A 20 candle-power gas lamp on the average gave less light than a 20 candle-power electric lamp, for the unit in the gas industry was based on a different standard and was smaller. Now the unit of candle-power is the same for gas and electric light, and every manufacturer and every lighting company is on the same basis, for all get their standards, directly or indirectly, from the bureau.

Often tests are made to settle disputes, either concerning the accuracy of instruments or concerning the performance of a machine sold under guarantee. The confidence that has frequently been expressed in the justness and impartiality of the bureau's decisions, when thus acting as a court of appeal, has been gratifying to the officers of the bureau.

5. COOPERATION WITH ENGINEERING SOCIETIES

The bureau cooperates with many engineering societies and foreign laboratories

in the work of standardizing and unifying practise, defining terms and improving nomenclature, working out uniform specifications and methods of tests, etc. In this work the division of Electricity, Magnetism and Photometry comes especially into contact with the American Institute of Electrical Engineers, the Illuminating Engineering Society, the Society for the Testing of Materials, the American Committee of the International Electrotechnical Commission and the International Committee on Electrical Units and Standards. The bureau is represented on the council or committees of all of these bodies, and each year many subjects arise that come within the field of the bureau's activities, and in the handling of which its representatives can cooperate. Reference was made above to the new tables of resistance for annealed copper wire. Heretofore, the English, German and American tables have all been different, not only for resistivity, but also for temperature coefficient, and two different densities were in use. Through the efforts of two of the above-mentioned bodies and the Bureau of Standards acting together in the negotiations with foreign laboratories and scientific societies, we are assured in the near future of international uniformity in all these quantities. Much has been accomplished also in securing international uniformity in electrical units, a common photometric unit in England, France and America, in comparing and standardizing measurements of electrical and magnetic quantities between national laboratories, etc.

The preparation of standard specifications for various kinds of materials is an important work, in which the bureau cooperates with the engineering societies and with the departments of the government.

6. COOPERATION WITH THE DEPARTMENTS OF THE GOVERNMENT

In addition to its cooperation with the departments of the government in the direction just noticed, and in doing testing in considerable quantity, the bureau cooperates with the departments also in other ways. With the War and Navy departments it cooperates in experimental work on radio-telegraphy, and several rooms in the bureau's laboratory are occupied by representatives of the signal corps of the army, and of the Navy Department, in this work. The bureau also renders technical assistance to the Bureau of Navigation, of the Department of Commerce and Labor, which is charged with the administration of the law requiring all passenger ships carrying fifty passengers or more to be equipped with radio-telegraphic apparatus. Its traveling inspectors visit the lamp factories and inspect for the various departments of the government a million electric lamps a year, taking samples for life test at the bureau.

7. DISSEMINATION OF INFORMATION

In addition to the scientific and engineering papers published in the *Bulletin*, and in the Bureau's Technologic Series thirty-one circulars of information have been published by the bureau on a variety of subjects, and among these nine have been prepared by the Electrical Division, and several others are in preparation. Among those issued may be mentioned "Standard Specifications for Incandescent Lamps," "A Proposed International Unit of Light," "Magnetic Testing," "Testing of Electrical Measuring Instruments," "Precision Measurements of Resistance and Electromotive Force" and "Transformer Specifications."

A large amount of time is expended in answering letters which request informa-

tion. These come from many classes of inquirers, asking many kinds of questions, some very easy and some very hard to answer. All receive careful attention, no matter how humble the writer or how simple the question. We in our turn write a great many letters asking for information, and we have to acknowledge the uniform courtesy accorded to such inquiries, and the valuable information often so obtained.

Much information is communicated also to those who call personally at the bureau, and this is naturally an increasing quantity. As the apparatus, methods of measurement and results for the most part are open to the public, many find it advantageous to make personal visits. An exception is made as to the results of tests for which a fee is paid, these being held as confidential and communicated only with the consent of the person for whom the test was made.

Enough has been said to show the great variety of the work in one division of the bureau, which may be taken as typical of all. It extends from the purely scientific investigations on the one hand to the most practical of engineering problems on the other. The work in electricity, magnetism and photometry is distributed among three different buildings, and needs more space. The new building now under construction, which will be 190×60 feet in floor area, with four stories and basement, will afford larger and better accommodations for this work.

In closing this necessarily incomplete account of the work of the electrical division of the bureau, let me say a few words as to the reasons for testing instruments and materials purchased by the government. Most people admit the advantage of such testing, but few appreciate how important it is, or how many sided is the question of

testing in connection with government purchases. It is of importance from a business standpoint, and as a matter of good engineering. It is also of great importance as contributing to good government.

8. REASONS FOR TESTING MATERIALS PURCHASED BY THE GOVERNMENT

1. The first and most obvious reason for testing instruments, machinery and materials purchased by the federal government is of course to insure the government getting what it pays for. But that is not the only reason, and in some cases it may not be the main reason. Such testing is done upon many kinds of materials, but for a concrete illustration we may think of electrical instruments or electric lamps.

(1) With the results of a thorough and impartial test at hand, a government engineer, charged with drawing specifications for a given kind of instrument or material, knows what performance can be secured by such instruments, or what properties can be expected in the given material, and hence is able to prepare the specifications intelligently.

(2) With the results at hand of tests on the instruments or materials of different makes, the purchasing officer knows what makers to invite to submit bids for government requirements. If those whose instruments or materials are unsuited for the given purpose are not permitted to bid, expense and trouble are avoided, both to the manufacturer and to the government.

(3) If the results of thorough tests are available, the purchasing officer can take account of the quality as well as the price in making awards of contracts. It often happens that any one of several makes of instruments or materials can be used, and it is necessary to know the differences in quality as well as the differences in price

in order to determine which bid is best. The practise of accepting the lowest bid regardless of quality often causes dissatisfaction both to those who bid for the government's business and those who use the articles purchased.

(4) If tests are systematically made, a conscientious purchasing officer is protected from charges of favoritism or collusion in the performance of his duty. His answer to such intimations, whether they come from dealers or those in authority, is the certified results of tests upon which he had relied. If the tests have been made in an impartial and well-equipped laboratory established for the purpose, the results are likely to be given greater weight, and the protection to the purchasing officer is greater, than if done by the bureau or department making the purchase. Purchasing under such a system of testing, the opportunity and the temptation to collusion between purchasing officer and contractor is greatly reduced. Such collusion is not frequent in the government service, but it has occurred, and it is desirable to reduce the opportunity for it to a minimum.

(5) Purchasing under a system of thorough and systematic tests protects administrative and purchasing officers from political pressure in connection with purchases, and members of congress are spared from the appeals of constituents in connection therewith. It has sometimes happened that a manufacturer or contractor on failing to secure a government contract feels that he has been discriminated against, and in good faith goes to his congressman or senator with his grievance. The latter is placed in an embarrassing position, between his desire to serve his constituent and his uncertainty as to the real facts in the case. A system of fair and thorough testing of materials in connection with public advertising removes almost entirely

any occasion for appealing to a member of the legislative branch of the government concerning business transactions in the executive departments.

(6) If the instruments or materials are delivered from time to time, tests are necessary in order to see that the deliveries are in accordance with the samples or the specifications. If deliveries are accepted without tests or inspection, or with inspection only, the door is opened for deception and fraud; honest dealers or manufacturers are at a disadvantage in competition with unscrupulous ones in dealing with the government; and it may result under such circumstances that the most reliable manufacturers will refrain from bidding on government business, leaving those who are willing to misrepresent their products to compete with one another for the government patronage. The government then becomes a party to fraudulent transactions, and to a greater or less extent tends to demoralize business. On the other hand, if careful inspections and tests are regularly made, and acceptances are conditioned on meeting the specifications, manufacturers often thereby become better acquainted with the properties of their own products, honesty and uprightness in business are encouraged, a standard of quality is set for the given instrument or material which helps other purchasers besides the government, and the whole industry may be greatly benefited.

(7) If the reports of such tests are communicated to the manufacturers, as they generally are, defects in the product are perhaps sooner discovered and sooner remedied, and if the government invites the cooperation of the manufacturers when undertaking tests of types of instruments or of materials, the tests are likely to be fairly conducted and the results representative.

(8) In these days of commercial combinations and gentlemen's agreements as to prices, it sometimes happens that the government can not secure competition in price, but finds that the bids from different manufacturers are identical in price. Here again, testing the product solves an otherwise serious difficulty, for it is generally possible even in this case to secure real competition as to quality, and this is quite as important as competition in price.

It is thus seen that there are many reasons for testing the thousands of kinds of instruments, machines and materials purchased by the government, and for doing this, in large measure at least, in a well-equipped institution set apart for that purpose. The Bureau of Standards has done considerable work of this kind, but the government's purchases are so varied and so vast, and so many requests for tests came from states, municipalities, and the public, that the work involved is very great, and only a fraction of the work is done which could be done with profit. Whether the bureau shall grow in the future as fast as the demands upon it for testing and investigation increase is uncertain. But if it does only a part of the work waiting to be done, and does that part well, it will amply justify its existence, and in so doing save the government and benefit the industries far more than the cost of its maintenance.

EDWARD B. ROSA

BUREAU OF STANDARDS

PROGRESS IN INDUSTRIAL FELLOWSHIPS

IN the issue of SCIENCE for Friday, May 7, 1909, I presented the main outlines and contemporary status of a scheme of industrial fellowships initiated by me in an article in the *North American Review* for May, 1907. Since this statement I have made no report to this journal.

I now present the establishment of a new

series of fellowships, not only at the University of Kansas, but at the University of Pittsburgh. The industrial fellowships so far established at the University of Pittsburgh and now in operation are as follows:

1. *Baking*.—\$750 a year for 2 years. Additional cash bonus of \$2,000. Fellow: Wilber A. Hobbs, A.B., University of Kansas, instructor in chemistry.

2, 3. *Abatement of the Smoke Nuisance (Multiple Fellowship)*.—\$12,000 a year for 2 years. Additional consideration, 49 per cent. collective interest. Fellows: Raymond C. Benner (senior fellow), Ph.D. University of Wisconsin, assistant professor University of Arizona; W. W. Strong (second fellow), Ph.D. Johns Hopkins University, Carnegie assistant and assistant in chemistry Johns Hopkins University. Other fellows to be appointed.

5. *On the Relation of the Pots to Glass in Glass-making and the Elimination of "Strea."*—\$1,500 a year for 2 years. Additional cash bonus of \$2,000. Fellow: Samuel Ray Scholes, Ph.D. Yale University, H. B. Loomis fellow in chemistry Yale University.

6, 7, 8. *Baking (wholly Independent of but with Acquiescence of No. 1) (Multiple Fellowship)*.—\$4,750 a year for 2 years. Additional consideration of \$10,000. Fellows: Henry A. Kohman (senior fellow), Ph.D. University of Kansas, holder of National Association of Master Bakers' fellowship; Charles Hoffman (second fellow), B.S. University of Kansas, laboratory assistant Yale University; Alfred Edward Blake (third fellow), B.S. New Hampshire College, assistant in chemistry Rensselaer Polytechnic Institute.

9. *Glue*.—\$1,200 a year for 2 years. Fellow: Ralph C. Shuey, B.S. University of Kansas, former industrial fellow University of Kansas.

10. *Soap*.—\$1,200 a year for 2 years. Fellow: Paul R. Parmelee, B.S. University of Kansas, curator of chemistry and pharmacy department, University of Kansas.

11. *Utilization of Fruit Waste*.—\$1,000 a year for 2 years. Additional consideration, \$10,000. Fellow: F. Alex. McDermott, George Washington University, of Hygienic Laboratory, Washington, D. C.

12, 13, 14, 15, 16. *Crude Petroleum (Multiple)*.—\$10,000 a year for 2 years. Collective interest of 10 per cent. Fellows: Raymond F. Bacon (senior fellow), Ph.D. University of Chicago,

chemist Bureau of Science, Manila, assistant chemist Bureau of Chemistry, Washington, D. C.; Lester A. Pratt (second fellow), M.S. New Hampshire College, instructor at New Hampshire College; C. W. Clark (third fellow), M.A. Ohio State University, assistant chemist Bureau of Chemistry, Washington, D. C.; Hugh Clark (fourth fellow), M.A. Ohio State University; Arthur H. Myer (fifth fellow), A.M. Leland Stanford University, assistant department of chemistry, Stanford; Fred W. Padgett (scholar), University of Kansas.

17. *Composition Flooring*.—\$1,500 a year for 2 years. 1 per cent. of sales for 5 years. Fellow: R. R. Shively, B.S. Oklahoma A. & M. College, assistant chemist Bureau of Chemistry, Washington, D. C.

18, 19. *Natural Gas (Multiple)*.—\$4,000 a year for 2 years. 5 per cent. of industrial results. Fellows: Clarence L. Speyers (senior fellow), Ph.D. Harvard University, Carnegie assistant Harvard University; Roy H. Uhlinger (second fellow), M.A. University of Pittsburgh, fellow in chemistry University of Pittsburgh.

20. *Cement*.—\$1,800 a year for 2 years. \$10,000 additional consideration. Fellow: J. F. MacKey, Ph.D. University of Toronto, former industrial fellow University of Kansas.

The fellowships above listed went into operation September 1 of the current year. They involve the work of twenty fellows and a salary list of \$39,700 a year for two years, or \$79,400 in all. The work is being conducted in a temporary but efficient building erected at a cost of about twelve thousand dollars.

At the University of Kansas, where this work has been in operation since 1907, I have to report the foundation of the following new fellowships, not yet published in SCIENCE:

10. *On the Chemical Treatment of Wood*.—\$1,500 a year for 2 years. Large additional consideration. Fellow: L. V. Redman, Ph.D., University of Toronto.

11. *On New Utilities for Borax*.—\$750 a year for 1 year. Fellow: B. C. Frichot, B.S., University of Kansas.

12. *On the Chemistry of Vegetable Ivory*.—\$1,500 a year for 2 years. Maximum cash bonus of \$2,000. Fellow: J. P. Trickey, A.B., New Hampshire College, University of Toronto.

13, 14. *On the Relation of Crude Petroleum to the Manufacture of Soap*.—\$2,750 a year for 2

years. Maximum cash bonus of \$5,000. Fellows: F. W. Bushong (senior fellow), Ph.D., former industrial fellow at University of Kansas; J. W. Humphreys (second fellow), A.M. University of Kansas.

15. *On the Chemistry of Gilsonite*.—\$750 a year for 1 year. Maximum cash consideration of \$2,000. Fellow: W. E. Vawter, A. B. University of Kansas.

16, 17, 18. *On the Chemical Treatment of Wood*.—\$3,900 a year. Owing to the remarkable progress of fellowship No. 10 during the first year, the donating company extended its value to \$3,900 a year and thus provided for the aid of two additional fellows. Fellows: L. V. Redman (senior fellow), Ph.D. University of Toronto; Frank P. Brock (second fellow), A.B. University of Kansas; Archie J. Weith (third fellow), A.B. University of Kansas.

Altogether, both at the University of Kansas and at the University of Pittsburgh, there

have been so far involved \$113,400 for direct expenditure in salaries in industrial research.

ROBERT KENNEDY DUNCAN

UNIVERSITY REGISTRATION STATISTICS

THE registration returns for November 1, 1911, of twenty-seven of the leading universities of the country will be found tabulated below. Seven institutions exhibit a decrease in the total enrollment (including the summer session) this year, viz., Chicago, Minnesota, Missouri, Nebraska, Northwestern, Texas and Yale, although in the case of Minnesota and Nebraska the apparent loss is due to a change of classification. The largest gains in terms of student units were registered by California (966), where the summer session showed an increase of 913 students, Columbia (527), Cornell (440) and

	Total Attendance November 1, 1911	Attendance Summer Session, 1911	Grand Total	Deduct Summer Session Stu- dents who Re- turned in Fall	Net Total, November 1, 1911	Total, No- vember 1, 1910	Total, No- vember 1, 1908	Total, November 1, 1903

Yale.....	3224	—	3224	—	3224	3287	3466	2990

¹In all faculties, excluding preparatory or extension department.

²These figures do not include the registration in the two branch schools of agriculture, nor in any of the short courses, some of which were included

in the previous years. The actual attendance this fall is practically identical with that of 1910.

³Certain classes of students counted in previous years must have been omitted in the total for 1911, since the institution reports a gain over last year.

Ohio State (386). Last year there were seven institutions that showed a gain of over three hundred students, California and Columbia being among the number. Omitting the summer session attendance, the largest gains have been made by Cornell (307), Ohio (282), Illinois (241), Columbia (223), Michigan (132), New York University (118) and Virginia (116). It will thus be seen that this year only four institutions exhibit an increase of over two hundred students in the fall attendance, as against seven in 1910 and eleven in 1909.

According to the figures for 1910, the twenty-seven universities included in the table ranked as follows: Columbia, Chicago, Michigan, Harvard, Pennsylvania, Cornell, Minnesota, California, Wisconsin, Illinois, New York University, Nebraska, Northwestern, Yale, Syracuse, Ohio State, Missouri, Texas, Kansas, Indiana, Tulane, Iowa, Stanford, Princeton, Western Reserve, Johns Hopkins, Virginia. Comparing this with the order for 1911, and leaving Minnesota and Nebraska out of consideration, we find that Columbia continues to maintain its long lead, that California has passed from the eighth to the second place, that Cornell has passed from the sixth to the third place, that Michigan and Harvard have each dropped down one place, Pennsylvania two places, and Chicago four, and that Wisconsin and Illinois have advanced a place owing to the change in the Minnesota figures. The balance of the institutions now rank in the following order: New York University, Ohio State, Northwestern, Syracuse, Yale, Nebraska, Missouri, Texas, Kansas, Indiana, Tulane, Iowa, Stanford, Princeton, Western Reserve, Johns Hopkins, Virginia. California is the seventh and Wisconsin the eighth institution to pass the five thousand mark. If the summer session enrollment be omitted, the universities in the table rank in size as follows: Columbia, Cornell, Michigan, Harvard, Pennsylvania, Illinois, Minnesota, California, Wisconsin, New York University, Northwestern, Yale, Syracuse, Ohio State, Chicago, Nebraska, Missouri, Kansas, Texas,

Iowa, Stanford, Princeton, Indiana, Western Reserve, Tulane, Virginia and Johns Hopkins, the order of the first ten institutions last year on this basis being Columbia, Minnesota, Michigan, Pennsylvania, Harvard, Cornell, Illinois, California, Wisconsin, New York University.

The detailed statistics by faculties will hereafter be given in the spring, in order that the final figures for the year may be provided instead of the preliminary registration only. The number of students entering in the second term at the larger institutions is growing constantly, and as a result the final enrollment frequently shows a considerable increase over that of November first. The changes in attendance, equipment, etc., will also be submitted at that time.

The fall enrollment at a number of prominent colleges (for men and for women) and schools of technology is given in the following table:

Institution November 1	1911	1910	1904
Amherst.....	464	502	472
Brown (incl. graduate school)....	933	930	988
Bryn Mawr (incl. graduate school).....	440	409	441
Dartmouth (incl. eng., med., grad., stud., and commerce)...	1,385	1,229	926
Haverford.....	164	150	146

RUDOLF TOMBO, JR.

COLUMBIA UNIVERSITY

SCIENTIFIC NOTES AND NEWS

PROFESSOR EDWARD C. PICKERING, director of the Harvard College Observatory, has been elected president of the American Association for the Advancement of Science, to preside at the meeting to be held at Cleveland, Ohio, beginning on December 30, 1912.

PROFESSOR E. L. THORNDIKE, of Teachers College, Columbia University, was elected

president of the American Psychological Association at the recent Washington meeting.

COLONEL WM. P. GORGAS has been elected president of the ninth Congress of American Physicians and Surgeons, which meets in Washington in May, 1913.

PROFESSOR H. L. FAIRCHILD, of the University of Rochester, has been elected president of the Geological Society of America.

THE following have been elected foreign members of the Royal Society: Dr. Johann Oscar Backlund, of Pulkowa, imperial astronomer of Russia; Dr. Heinrich Ritter von Groth, professor of mineralogy in the University of Munich; Heinrich Kayser, professor of physics in the University of Bonn; M. Joseph Achille Le Bel, of Paris, the chemist, and Klement A. Timiriazeff, professor of botany in the University of Moscow.

LORD CROMER and the Hon. Lionel Walter Rothschild have been elected fellows of the Royal Society under the statute which empowers the council once in every two years to recommend to the society for election not more than two persons who in their opinion have rendered conspicuous service to the cause of science.

DR. CARLOS FINLAY, of Havana, has been elected a corresponding member of the Paris Academy of Medicine.

It is stated in *Nature* that Professor G. Elliot Smith, F.R.S., professor of anatomy in the University of Manchester, has been awarded by the Paris Anthropological Society the Prix Fauvel, of one thousand francs, for his researches in the anatomy and physiology of the nervous system.

GOVERNOR DIX has requested the resignation of Dr. Alva H. Doty as health officer of the Port of New York. Two weeks before a largely attended meeting of physicians of the New York Academy of Medicine, presided over by Dr. Abraham Jacobi, had passed resolutions requesting the reappointment of Dr. Doty, and referring to the admirable manner in which he had filled the position for the past sixteen years.

PROFESSOR VON WASSERMANN, the bacteriologist, has been appointed honorary professor at Berlin.

PROFESSOR ZIEMANN has resigned the charge of the public health service in Cameroon, Africa, on account of his health.

E. W. RUST, A.B. (Stanford), formerly at the Southern California Laboratory, has contracted with the Peruvian government for eighteen months as first assistant entomologist. He arrived in Peru early in December.

MR. L. H. WORTHLEY, assistant state forester of Massachusetts, in charge of the moth work, has accepted a position in the Bureau of Entomology. He will proceed to Europe to study the conditions on the continent.

MR. FLOYD B. JENKS, assistant professor of agricultural education in the Massachusetts Agricultural College, has accepted an appointment in the Bureau of Education.

PROFESSOR FINKLENBERG, of Bonn, has assumed the direction of the hydrotherapeutic institute, Berlin, as successor to Professor Strasburger.

Nature states that the presentation of a testimonial to Mr. Henry Keeping on his retirement from the post of curator of the Geological Museum, Cambridge, took place in the Sedgwick Museum on Saturday, December 2, when Professor T. McKenny Hughes handed him a purse subscribed by old friends and students in recognition of his long and valuable services. Mr. Keeping entered upon his duties as curator fifty years ago under Professor Sedgwick in the old Woodwardian Museum, where the geological department was located until its removal into the Sedgwick Museum in 1904.

PROFESSOR W. E. CASTLE, of Harvard University, who has left Cambridge to visit a number of countries of South America, chiefly Peru, wishes to obtain certain rodents for experimental work in genetics at the Bussey Institution. Part of the expenses of Professor Castle's trip are borne by the Carnegie Institution. He expects to return to Cambridge about February 1, although his trip may be prolonged until the first of March.

HIRAM BINGHAM, professor of Latin-American history at Yale University, has returned from a six months' journey of exploration in Peru.

It is stated in *The Condor* that Mr. W. Leon Dawson spent a portion of the field season in out-door work contributory to his projected "Birds of California." The Farallone Islands and the Mount Whitney region were visited.

MR. W. BATESON, F.R.S., director of the John Innes Horticultural Institution at Merton, Surrey, has been appointed the next Herbert Spencer lecturer at Oxford. The subject of the lecture, which will be given on February 28, is "Biological Fact and the Structure of Society."

We learn from *Nature* that the dean of Westminster, with the full concurrence of the chapter, offered to the family to permit the interment of Sir Joseph Hooker's ashes in the abbey, on the condition that his remains were previously cremated. The family has felt obliged to decline the offer as it was Sir Joseph's express wish that he should be buried by the side of his father at Kew. The funeral took place at Kew Parish Church on December 15.

MR. WILLIAM THYNNE LYNN, formerly assistant in the Royal Observatory, Greenwich, and the author of various contributions to astronomy, especially on its history, died on December 11, aged seventy-six years.

DR. DAVID STARR JORDAN, of Stanford University, one of the vice-presidents of the first international eugenics congress to be held at the University of London from July 24 to 30, 1912, has accepted the presidency of the consultative committee for the United States. The officers of the congress hope that it will result in a far wider recognition of the necessity for an immediate and serious consideration of eugenic problems in all civilized countries. The proof of this necessity must be based on the laws of heredity, on the history of the changes in racial characteristics in the past, and on what is known concerning the effect of all the many biological and social factors which tend either to improve or de-

teriorate the innate qualities of mankind. If this field should be covered in a wide and comprehensive manner in the papers presented to the congress, including an adequate discussion of the general nature of the reforms, moral and legislative, necessary for insuring the progress of the race, the records of the proceedings would form a presentment of the case for eugenic reform which would assuredly be of great value to both the legislator and the social reformer. To achieve such a result should be the main object, rather than the attempt to make the congress an arena for the discussion of academic questions mainly of interest to scientific investigators.

THE Society for Biological Research of the University of Pittsburgh held the first of its special meetings for the year 1911-12 on December 14, at which time Dr. George Neil Stewart, professor of experimental medicine and director of the Cushing Laboratory at Western Reserve University, presented to the society the results of some of his recent work on the rate of the blood-flow in man. This plan of special lectures was inaugurated during the year 1910-11, by addresses on the "Hypophysis," by Dr. Harvey K. Cushing, of Johns Hopkins University, and on "Habit," by Dr. J. George Adami, of McGill University.

THE President of Venezuela has issued a decree creating a National Bureau of Sanitation. Under its auspices will be inaugurated an Institute of Hygiene, which will be composed of a laboratory of bacteriology and of parasitology, a veterinary department, and a central station of disinfection. The staff of the bureau will be composed of a director, a subdirector, a bacteriologist, an engineer, a biologist, a veterinary surgeon, an inspector general, two technical aids, a secretary and two laboratory assistants.

THE Boston *Transcript* states that a bill intended to give effect to the convention between the United States, Great Britain, Japan and Russia for the preservation and protection of the fur seals in the waters of the North Pacific Ocean will be considered by the house committee on foreign affairs very soon after

congress reconvenes. The treaty was concluded here last July and the final exchanges of ratifications between the governments ended two weeks ago. It now remains necessary only for the required legislation to be enacted. The bill to put the terms of the treaty into effect declares that no citizen of the United States shall kill or capture fur seals in the Pacific Ocean or seas of Bering, Kamschatka, Okhotsk or Japan north of the thirteenth parallel of north latitude, or kill sea otter in any of the waters beyond three miles from the United States shore line. Further, it is recited that no citizen of the United States shall equip or aid in equipping vessels to be used in pelagic sealing in these waters; that the importation of fur seal skins taken in those waters be prohibited except such as have been taken under authority of the respective governments parties to the convention to which the breeding grounds belong. Heavy penalties are provided by the bill for violations of its provisions.

THE value of the total mineral output of Alaska in 1911 is estimated at \$20,370,000, compared with \$16,883,678 in 1910. The gold output in 1911 is estimated to have a value of \$17,150,000; that of 1910 was \$16,126,749. It is estimated that the Alaska mines produced 22,900,000 pounds of copper in 1911, valued at about \$2,830,000; in 1910 their output was 4,241,689 pounds, valued at \$538,695. The silver production in 1911 is estimated to have a value of \$220,000, compared with \$85,236 for 1910. The value of all other mineral products in 1911, including tin, marble, gypsum and coal, was about \$170,000, an increase over that of 1910. By using the above estimates for the output of 1911, the total value of Alaska's mineral production since 1880, when mining first began, is found to be, in round numbers, \$206,800,000, of which \$195,950,000 is represented by the value of the gold output. The total production of copper in Alaska since 1901, when systematic mining of this metal began, is about 56,700,000 pounds, valued at about \$8,170,000.

MR. N. HOLLISTER, assistant curator of the division of mammals, U. S. National Museum,

announces the discovery of four new animals from the Canadian Rockies, in a paper just published by the Smithsonian Institution. During last summer a small party of naturalists from the Smithsonian Institution accompanied the expedition of the Alpine Club of Canada, to the Mount Robson region, where they made the first natural history collection ever taken in that vicinity. The paper mentioned above is the first publication issued by the institution on this expedition, although Mr. J. H. Riley, a member of the party, has written a description of two new species of birds discovered on the trip, which has recently been published in the *Proceedings* of the Biological Society of Washington; both of the birds are of the sparrow family, one a song sparrow, and the other a fox sparrow. The natural history work of the expedition was under the charge of Mr. Hollister. He paid especial attention, however, to the mammals, four of which he describes, a chipmunk, a manteled ground-squirrel and two bats. All the specimens come from the neighborhood of Mount Robson, which lies in one of the wild and unexplored parts of British Columbia, at about 14,500 feet elevation.

THE Bureau of American Ethnology is preparing a new work which will form a "Handbook of Aboriginal Remains in the United States, and will have to do with the ancient abodes, camps, mounds, workshops, quarries, burial places, etc., of the Indian tribes. In connection with this work, Mr. F. W. Hodge, ethnologist in charge of the Bureau of American Ethnology, is sending letters of inquiry to all persons thought to have any knowledge of the subject of this undertaking, as well as to all institutions and societies interested in American archeology and ethnology. The letter requests all information respecting the location, character and history of the remains left by the Indians, or other indications of their former occupancy. In 1891 a catalogue of prehistoric works east of the Rocky Mountains was published, but that work is both out of date and out of print. It was compiled by Dr. Cyrus Thomas and

several collaborators. A large territory was covered in the first book and judging from the large map of the eastern United States, the parts of this country most densely populated by the aborigines must have been the basins of the Mississippi and Ohio rivers and the southern shores of the Great Lakes, although there are indications of many settlements on the Atlantic coast, especially in Florida. A large map showed all the locations, and smaller maps, of which there was one for each state, indicated the nature of each site by a special symbol. In the cartographic list, one found the meanings of the symbols readily; a single house drawn in outline represented a wooden lodge, while two houses represented a village; a grave was indicated by a special figure; a mound by the same figure reversed, and so on; enabling one, with a little study, to see at a glance exactly what was located at a certain point. It is not expected that the prospective work on Indian antiquities will be issued for many months. Following the precedent of the old report, the new one in completion, will show, to even a greater and more extensive end, all available information. It is proposed to classify the former Indian remains by states and counties, and to illustrate the publication with maps, photographs and drawings.

UNIVERSITY AND EDUCATIONAL NEWS

THE University of Edinburgh has received from the trustees of the estate of Mr. Robert Irvine the sum of £30,000, to establish a chair of bacteriology.

THE Cambridge council has voted the closing of the streets which cross the fifty acres of land fronting on the Charles River which the Massachusetts Institute of Technology proposes to purchase.

A NEW plan for the administration of the College of Agriculture, Cornell University, has been enacted by the university board of trustees to go into effect on January 1, 1912. The management of the college will be subject to the general supervision and control of the full board of trustees, and the immediate

supervision, instead of being in the hands of the executive committee of the board, as now, will be entrusted to a special committee of eleven persons to be known as the Agricultural College council. Director Bailey has consented to remain at the head of the college long enough to put the new plan in substantial operation.

THE Annual Farmers' Short Course at the University of Missouri will be given this year beginning January 8 and continuing throughout the week. It is planned to give six short courses on soils and farm crops, animal husbandry, farm management, dairy husbandry, horticulture and poultry husbandry. The class rooms and laboratories of the Agricultural College will be thrown open during this week to the farmers of Missouri. The entire teaching force of the college, consisting of more than forty men, will, by lecture and demonstration, give instruction in the subjects and will describe the experiments conducted by the Experiment Station. The state board of agriculture, cooperating with the college, has provided for the evening lectures. President K. L. Butterfield, of Massachusetts; Dean H. L. Russell, of Wisconsin; Jos. E. Wing, of Ohio; A. N. Abbott, of Illinois; Herbert Krum, of Kentucky; Uriel W. Lamkin, of Missouri, and many others will address the farmers. The annual Farmers' banquet, given by the College of Agriculture and consisting largely of products grown on the college farm, will be given Friday night, January 12. The beef will be from an international prize winner, the cream and butter from the Dairy Department and fruits and vegetables from the Department of Horticulture. Governor Herbert S. Hadley will be present during the week.

THE minister of education has laid before the Hungarian parliament a bill which provides for the erection of two new universities in Hungary, in the cities of Pressburg and Debreczin.

PROFESSOR E. G. MONTGOMERY, of Nebraska University, has been appointed professor of

farm crops in the College of Agriculture of Cornell University.

DR. H. BASSETT, of the University of Liverpool, has been appointed professor of chemistry at University College, Reading.

DR. W. R. BOYCE GIBSON, lecturer in philosophy at the University of Liverpool, has been appointed professor of mental and moral philosophy at the University of Melbourne.

DISCUSSION AND CORRESPONDENCE

"GENOTYPES," "BIOTYPES," "PURE LINES" AND "CLONES"

IN a recent issue of SCIENCE¹ Dr. Jennings calls attention to a double meaning which has been given to the word "genotype" by several recent writers, myself among them, and points out the desirability of limiting the word to the meaning assigned to it by its originator, Dr. Johannsen.

As one of the chief offenders, I wish to publicly repent my misuse of the term and to heartily join in the movement to limit the word "genotype" as used in the literature of genetics, to the fundamental hereditary constitution of an individual. The use of this word both for the hereditary constitution and for the group of individuals possessing an identical hereditary constitution, will lead to much confusion if continued.

The word which Dr. Jennings says is much needed "for a concrete, visible group of organisms" "all with the same hereditary characteristics," has been already supplied. In a symposium on the "Aspects of the Species Question" before the Botanical Society of America at Chicago, January 1, 1908, I pointed out² the same need and expressed a hope that some one would "come forward with an acceptable short designation" for these "elementary forms" which had been classified by de Vries as "elementary species" and "varieties." A few months later I discovered that my wish had been fulfilled before its utterance, by Dr. Johannsen, and his word "biotype"³ was immediately adopted in my

paper on "The Composition of a Field of Maize"⁴ and made a part of the title of my work on "*Bursa bursa-pastoris* and *Bursa Heegeri*: Biotypes and Hybrids."⁵ In view of these facts there was no excuse for my use of the word "genotype" in a taxonomic sense.

Dr. Jennings also calls attention to an important misuse of the expression "pure line," and here I must again admit a certain amount of guilt, as I was probably the first to include under this term groups of individuals related through the process of budding or any other method of vegetative reproduction. In 1904 I wrote:⁶

By the "pure line" Johannsen means a series of individuals related only through the process of self-fertilization. On *a priori* grounds it seems proper to apply the term to every series of individuals that do not combine elements of two or more ancestral lines through the equivalent of a sexual process. Thus, so far as hereditary qualities are concerned, there should be no reason to expect in a self-fertilizing population conditions different from those in a population related through budding or other method of vegetative reproduction, provided, of course, that the self-fertilizing population has not been so recently modified by a cross as to allow the analysis and recombination of characters derived from different ancestral lines.

For this early departure from "the narrow path" I have in part atoned in my recent paper on the "Genotypes of Maize,"⁷ by referring to the vegetatively reproduced potato and paramecium as "clonal varieties," in contradistinction to the self-fertilizing "pure

¹This word was first proposed in 1905 in "Arvelighedslærens Elementer," the Danish fore-runner of "Elemente der exakten Erbligheds-lehre," and was first used in English at the Third International Conference on Genetics in 1906. (See Report Third International Conference on Genetics, p. 98, 1906.)

²Report American Breeders' Association, IV., 296-301, 1908.

³Carnegie Institution of Washington Publication No. 112, 1909.

⁴*Torreyia*, V., 22, February, 1905.

⁵*Amer. Nat.*, XLV., 234-252, April, 1911.

²*Amer. Nat.*, XLII., 278, May, 1908.

lines" of beans, barley, etc. I might equally well have called them simply "clones," as "clonal varieties" and "clones" should have identical meaning. The word "clone" (Greek *κλων*, a twig, spray, or slip) was proposed by Webber* for "groups of plants that are propagated by the use of any form of vegetative parts, such as bulbs, tubers, cuttings, grafts, buds, etc., and which are simply parts of the same individual seedling." I believe that no violence will be done by extending this term to include animals which are similarly propagated by any asexual method, and I suggest the general adoption of the word "clone" for all groups of individuals having identical genotypic character,[†] and arising by asexual reproduction of any sort, including apogamy (*i. e.*, so-called "parthenogenesis" unaccompanied by a reduction division).

For the purposes of my discussion in 1904 the distinction between "pure lines" and "clones" was of no consequence, because the particular hereditary principle then under consideration was common to both. The same thing is no doubt true of many of the recent investigations of others, but it is well to remember that there are certain fundamental differences between "pure lines" and "clones," which render it very important to maintain the distinction between them. I will mention but two of these differences by way of example: (1) In the "clone" it is possible to retain as a permanent feature of the group any purely heterozygous character, as for instance the vigorous constitution dependent upon the stimulation of heterozygosis; such a phenomenon is impossible in the "pure line." (2) When clonal individuals reproduce sexually, either by self-fertilization or by crossing with other individuals, they need not, and usually do not, produce genotypically equal offspring, because the individuals of the

"clone" are not necessarily homozygous, as the individuals of the "pure line" generally are. The "clones" of horticultural plants are notorious for the heterogeneity of their seedling offspring. The investigator of intermittently parthenogenetic organisms like aphids, rotifers and Hieracium, and of intermittently vegetatively produced organisms like paramecium and many plants, can not properly assume that their races are genotypically pure in the sense that they are homozygous, while the worker with "pure lines" can make such assumption with small probability of error, in case his self-fertilizations have been controlled with adequate care during a sufficiently large number of generations.

There is another prevalent misconception regarding "pure lines," to which attention needs to be called. The word "pure" in this connection does not refer to the genotypic equality of the individuals, but only to the exclusion of all crossing as a source of genotypic differentiation.

In Dr. Harris's criticism[‡] of Roemer's work with peas, he points out with very evident satisfaction that two of Roemer's populations are historically traceable to individual selections and that they are therefore really "pure lines" (*i. e.*, providing, of course, that those originally selected individuals were strictly homozygous, and that no chance crossing has taken place since). If no genotypic changes can take place within the "pure line" all evolution is impossible in the large number of forms which naturally maintain "pure lines" by obligate self-fertilization. The only point to be made in regard to this feature of Roemer's results, is that, if his populations were really "pure lines," the numerous distinct biotypes he discovered by the "pure line" method in those populations, were the result of mutations which have taken place since the original selections were made. The occurrence of such mutations does not affect in the least the value of the genotype theory, nor the importance of the "pure line" method for the study of heredity.

* SCIENCE, XVIII., 501-503, October 16, 1903. For a discussion of the spelling of the word "clone" see SCIENCE, XXII., 89, July 21, 1905.

† This restriction is necessary in order to avoid confusion through the appearance of bud-mutations. Such a mutation if propagated vegetatively represents the origin of a new clone.

‡ Amer. Nat., XLV., 686-700, November, 1911.

Definitions:

Genotype, the fundamental hereditary constitution or combination of genes of an organism.

Biotype, a group of individuals possessing the same genotype.

Pure line, a group of individuals traceable through solely self-fertilized lines to a single homozygous ancestor.

Clone, a group of individuals of like genotypic constitution, traceable through asexual reproductions to a single ancestral zygote, or else perpetually asexual.

GEO. H. SHULL

HISTORY OF MATHEMATICS IN THE RECENT EDITION OF THE ENCYCLOPÆDIA BRITANNICA

THE new edition of the Encyclopædia Britannica contains numerous articles which purport to deal with the history of various branches of mathematics. None of these have been written by specialists in this field and the articles bear abundant evidence of this fact. The history of mathematics may well ask of the editors of such an encyclopedia the same care in the selection of writers on these topics as that exercised in the selection of writers in other fields, ably represented in general in the Britannica by the leading scholars of the world.

In a recent issue of SCIENCE (December 1, 1911) Professor G. A. Miller has called attention to certain inaccuracies and errors, especially with reference to the theory of numbers and of groups. It seems to me unfortunate, in view of the general worthlessness of the historical passages, that Professor Miller has incidentally chosen for criticism one of the few correct statements. The passage in question occurs on page 867 in volume XIX., in the article on "Numerals" in which the writer states that our present decimal system is of Indian origin. Attention is rightly called by Professor Miller to the fact that the zero appeared in Babylon long before it appeared in India, although the writer on "Numerals" seems to be unaware of this. However, the date is not 1700 B.C., as Professor

Miller states, but more than a thousand years later. Photographic reproduction of Babylonian tablets containing the zero appear in F. X. Kugler's "Die babylonische Mondrechnung," Freiburg i. Br., 1900, and these tablets date from the centuries just before the Christian era. Furthermore, no historian of mathematics has made the claim that modern arithmetic is derived from the Babylonian arithmetic, as Professor Miller implies, but there is general agreement that our arithmetic comes to us from the Hindus through the Arabic writer (c. 825 A.D.) Mohammed ben Musa Al-Khowarizmi. This subject is fully discussed in "The Hindu-Arabic Numerals," Smith and Karpinski, Boston, 1911.

The article on "The History of Mathematics," Vol. XVII., pp. 882-883, is too brief to invite comment. The incorrect statement is made: "The medieval Arabians invented our system of numeration." Reference is given only to the works of Cantor ("1st Bd.," "2d Bd." and "3d Bd.") and to W. W. R. Ball's "A Short History of Mathematics," London, 1888, and subsequent editions. The latter work is in no sense an authority on the subject.

The articles on "Algebra, History," Vol. I., pp. 616-620, and "Geometry, History," Vol. XI., pp. 675-677, contain so many inaccuracies and so much misinformation that selection becomes difficult. I will devote myself more particularly to the longer article on the history of algebra.

Some ridiculous statements made by Peter Ramus in his algebra of 1560 are quoted. Thus Ramus says: "There was a certain learned mathematician who sent his algebra, written in the Syriac language, to Alexander the Great, and he named it *almucabala*, that is, the book of dark or mysterious things, which others would rather call the doctrine of algebra . . . and by the Indians . . . it is called *aljabra* and *alboret*." This nonsense, evident on its face, as *almucabala* and *aljabra* are Arabic words, is taken somewhat seriously by this writer in the Britannica. "The uncertain authority," he says, "of these statements, and the plausibility of the preceding explana-

tion, have caused philologists to accept the derivation from *al* and *jabara*." The "preceding explanation," to which reference is made, is the correct one, viz., *algebra* from the first part of the title of Mohammed ben Musa's work on the subject.

Very evidently the writer has only second-hand information about the works of this great Arabic writer to whom the mathematical world is indebted for its knowledge of the Hindu numerals and also for the first systematic treatise on algebra. This is the more to be regretted, coming from Cambridge, since the unique copy of an early (twelfth century) Latin translation of Mohammed ben Musa Al-Khowarizmi's arithmetic is in a Cambridge library and the unique copy of the Arabic algebra is in Oxford and was translated into English in 1831 by F. Rosen. The arithmetic was published by Boncompagni, "Trattati d'Arithmetica," Rome, 1857. The writer in the Britannica regards the two as a single work and his comments on the indebtedness to Greek and Hindu sources are, of course, worthless.

Incorrect is the assertion that the thirteen books of Diophantus's "Arithmetica" are not lost, but this statement, it is only fair to say, may be due to a misprint. Bhaskara, a Hindu mathematician of the twelfth century, made great advances over the algebraic work of Brahmagupta (seventh century), although the Britannica states the contrary. John Pell's algebra of 1668 does not exist nor did he anywhere present the solution of the so-called Pellian, $x^2 - ay^2 = 1$. Pell did in 1668 have in print, simply under his initials, some comments on Brouncker's translation of Johann Heinrich Rahn's "Algebra." To Simon Stevin of Bruges is ascribed the publication of "an arithmetic in 1585 and an algebra shortly afterwards." Both were combined in one volume in 1585, as D. E. Smith shows in the "Rara Arithmetica," Boston, 1909, pp. 386-388. Stevin's fame as the first writer to give an exposition of decimal fractions seems not to be known to this writer, for the statement that Stevin "considerably simplified the notation for decimals" is wide of the mark.

Approaches to decimal fractions appeared before Stevin, but no exposition and no notation for Stevin to simplify.

The revival of the study of algebra in Christendom is incorrectly attributed to Leonard of Pisa (1202 A.D.). Robert of Chester, an Englishman living in Segovia, Spain, translated into Latin in 1145 A.D. the Arabic algebra of Mohammed ben Musa. Only a little later Gerard of Cremona treated the same work and about the same time Plato of Tivoli translated into Latin a work dealing with quadratic equations by Savasorda (twelfth century). The revival of mathematics in Christendom begins with these men and others who like them were occupying themselves with translations from the Arabic. The statement that the work of Leonard "contains little that is original, and although the work created a great sensation when it was first published, the effect soon passed away and the book was practically forgotten," is as false as it is ridiculous.

Now this writer turns immediately to discuss Luca Paciolo and then states: "These works are the earliest printed books on mathematics." How this glaring blunder "got by" the editors is difficult to understand. Leonard of Pisa's work was not in print until 1857, when Prince Baldassare Boncompagni published it and even Paciolo's "Summa de Arithmetica" did not appear until 1494. The first printed arithmetic is probably that of Treviso, 1478. Between that time and 1494 many important works appeared. No less than three editions of Pietro Borghi's arithmetic (1484, 1488 and 1491) and some six editions of the three different works on arithmetic by J. Widmann (1488, 1489, 1490, 1493), are included among these books. The "Algorismus" by John Halifax (Sacrobosco) appeared in two editions (1488 and 1490?). Philip Calandri published in 1491 an arithmetic with illustrated problems and Francesco Pellos (Pellizzati) got out an arithmetic in the year that Columbus discovered America. Peurbach's Algorismus (1492) and others could be added to this list.

The transliteration of Arabic names is en-

tirely original, as, for example, Tobit ben Korra for Thabit ben Qorra.

The most amusing statement is, "Fahri des al Karhi, who flourished about the beginning of the eleventh century, is the author of the most important Arabian work on algebra." Now Al-Fakhri, or Fakhri, is, indeed, the title of an Arabic work on algebra by one Abu Bekr Mohammed ibn Al-husain Al-Karkhi, or Al-Karkhi, for short. But the *des* seems, at first, unexplainable. The probability is that the *des* is German and some chance reference in German to the Fakhri des Al-Karkhi, the Fakhri of Al-Karkhi, undoubtedly accounts for this Farhi des Al Karhi.

Equally bad from a mathematical point of view is the surprising statement that "the Arabs accomplished the general solution of numerical equations."

The shorter article by the same writer on "Geometry, History," contains, of course, fewer errors. We must regard it as fortunate, in view of the errors I have shown and others not noted in the article on the history of algebra, that there is no article on the history of arithmetic. In pleasing contrast to these articles mentioned is the summary of the history of trigonometry by E. W. Hobson.

The one man best qualified to write a summary of the history of algebra and also of geometry is undoubtedly Sir Thomas L. Heath, sometime fellow of Trinity College, Cambridge. Even in 1910 the Cambridge University Press published a second edition of Heath's "Diophantus" and in 1908, Heath's "The Thirteen Books of Euclid's Elements," in three volumes. We may well express our surprise that the fame of Sir Thomas Heath should not be known to his Alma Mater, which stands sponsor for the encyclopedia, and that his aid was not sought for the history of mathematics in the Britannica.

L. C. KARPINSKI

ANN ARBOR, MICH.

DEVASTATION OF FORESTS IN THE WHITE MOUNTAINS

To those who have supposed that the Weeks bill for the preservation of the Appalachian

forests has settled a long-debated question, and that the advocates of the measure may now take a rest, secure in the belief that its execution is in the hands of a scientific man, armed both with authority and with knowledge, the article by Winthrop Packard in the *Boston Transcript* for October 7, 1911, stating the results of his exploration of the White Mountain region during the past summer will be a distinct shock.

"Lumbering," says Mr. Packard, "used to be a winter job, but there is no let-up in the rush now on to get the last spruce off the high levels of the White Mountains." The Weeks bill "is still about to work. But meanwhile the only part of it which is really working is the joker . . . which makes it indefinitely in-operative." An "innocent little paragraph in the Weeks bill says, in effect, that the head of the United States Geological Survey shall decide what areas are to be reserved along the head waters of the navigable rivers."

"Meanwhile, whether it affects the navigation of the Connecticut, the Androscoggin, the Saco and the Merrimac or not, the last of the good black growth of spruce, fir and hemlock is rapidly coming off the higher slopes of the Presidential Range and the lesser ranges that surround it."

"The best of the beautiful primeval forest is still above the high-water mark of this cutting, but it will take only a winter or two to encompass its downfall, and the investigations of the Geological Survey may probably be depended upon to hold the Weeks bill by the throat for that length of time, if not forever.

"The largest body of spruce left within sight of Mount Washington is that which lies at the head of the Rocky Branch Valley, between the Montalban Range on the west, the Rocky Branch Ridge on the east and Boott's Spur. . . . Here are some square miles of splendid black growth. . . . It is a virgin forest which one might suppose would last because of its inaccessibility. It is walled in by mountains on three sides and is sixteen miles up a tremendously rough valley from the south. This valley is drained by a tributary

he Saco, a stream so capricious and boulder-strewn that it would be an impossibility to drive logs down it. But spruce and hemlock are exceedingly valuable nowadays, and, however, that Weeks bill threatens—or would have eaten if it were not for that little joker—prevent the slaughter of trees so near Mount Washington. So a lumber railroad has been run with great energy up to the very center of this last refuge of the forest primeval. In the Crawford Notch the cutting has been carried as far up as the Frankenstein estate. "The whole easterly slope of the White Mts. among the valleys among the hills of this range have been denuded. Indeed, from the summit of Lafayette almost to the eye can see of the lower and western part of the Pemigewasset Valley has been swept clean and left a leafless, brown desert of slash. So from Carrigan Summit shows on the southerly slopes of Bemis, Madison, Lowell and Nancy."

It is evident from the above that the cutting of the forest is progressing at an unprecedented rate, and this, not merely on the lower and more gentle slopes where there is a possibility that the growth of spruce may be renewed, but also on the upper and steeper inclines where the forest, when once removed, is gone, if not forever, still at least until the next Ice Age wipes out the relics of human folly, renews the mantle of drift, and restores, after the recession of the ice, those climatic conditions which make the initiation of evergreen forests possible in such situations.

At the conference of governors, called by President Roosevelt to consider the conservation of our natural resources, after reciting the axiom: "The great natural resources supply the material basis upon which our civilization must continue to depend and upon which the perpetuity of the nation itself rests," the conference made the following unanimous declaration:

"We agree, in the light of the facts brought to our knowledge and from information received from sources which we can not doubt, that this material basis is threatened with

exhaustion. Even as each succeeding generation from the birth of the nation has performed its part in promoting the progress and development of the republic, so do we in this generation recognize it as a high duty to perform our part; and this duty in large degree lies in the adoption of measures for the conservation of the natural wealth of the country." It was further declared that "this conservation of our natural resources is a subject of transcendent importance, which should engage unremittingly the attention of the nation, the states and the people in earnest cooperation."

All of this is matter for consideration in the light of science. As abstract questions, these declarations received universal acquiescence; but diversity of opinion arises in their application, and here we enter upon a sphere of action where science and politics must combine. Distasteful as it may be to men of science to enter into the sphere of politics, the lesson which the laborers have been slowly learning, that the needs of industry receive no attention until pushed to the center of the political arena, must apparently be taken home by science also.

One of the declarations of the governors reads: "That sources of national wealth exist for the benefit of the people, and that monopoly thereof should not be tolerated." Here this honorable body touches the crux of the whole matter.

As soon as remedial legislation is attempted, the forces of monopoly show themselves to be stronger than science, stronger than governors or presidents. In fact, there is only one power that is greater—that of the people. Whenever the nation becomes so thoroughly aroused that its people act together as one man, monopoly will be overthrown. Until that time arrives, there is need for science to continue a campaign of education and to continue it *unremittingly* as the governors advise.

After the first flush of enthusiasm has cooled, look for reaction and apparent back track to make way for the next wave of advance. The need of a new movement is

already immanent. Though the campaign of education may flag, the exploiters of the nation's resources, who act without regard to ultimate consequences and for self-interest only, anxious lest their special privileges may be curtailed, are not letting the grass grow under their feet.

It becomes necessary for men of science to reiterate the fundamental facts, which they can do in the present instance with the certainty that scientific prognostications anent the passing of the forest and its resulting woes can not be made too loud or too often. The American Association for the Advancement of Science, whose memorial in 1873 was one of the beginnings of the present conservation movement, could not do a better thing than to present at its coming session another memorial to Congress, recounting the lessons which the engineers have been learning.

Professor Willis L. Moore, in his report as Chief of the Weather Bureau for 1909-10 (p. 18) says: "After an elaborate research into all available data, the Weather Bureau, in company with many eminent engineers, concludes that on the principal rivers the floods are not higher or longer continued or the low water lower than forty years ago, while other persons hold to the opposite." Nothing whatever is said as to changes in forestation of the river-basins investigated during the forty years, a point on which Professor Swain has commented in his review¹ of another work by the same author. In the more thickly settled parts of the country, deforestation was already far advanced forty years ago. Attention to earlier records shows a very different condition.

Mr. Joseph B. Walker, writing in 1872, said that "the rapid destruction of the forests" of New Hampshire was then "painfully apparent everywhere"; and in 1891 the same author said: "The volumes of our streams are less

equable than formerly. In summer they are greatly reduced. Many brooks whose flow was once perennial are no longer to be found for one half of the year. This fact is due to the total or partial denudation of the land from which they flow. So serious an evil had this become, some thirty or forty years ago, that the manufacturing companies upon the lower part of the Merrimac were forced to construct vast storage reservoirs, at great expense, which can be drawn upon as water is wanted. Winnepesaukee Lake and Long Pond are two of these. Total denudation at the source of our streams would convert them into destructive torrents in spring and their channels into dry ditches for the rest of the year." The last is of course an inference, but one that is not improbable.

Similar occurrences have taken place in central New York. "With the clearing away of the forests and the burning of the forest floor came a failure of canal supply that necessitated the building of costly dams and reservoirs to replace the natural ones which the fire and axe had destroyed. The Mohawk River, which for years had fed the Erie Canal at Rome, failed to yield any longer a sufficient supply, whereupon the Black River was tapped at Forestport, and its whole volume at that point diverted southward to assist the Mohawk in its work." The reports of the superintendent of public works in New York State, thirty or more years back, reiterate the progressive failure of the water supply and appeal for the protection of the forests. We hear less of these complaints to-day simply because the railroads are in full control and many of the early canals are abandoned. But the time will surely come when this policy will be recognized as a mistake.

B. E. Fernow, in a paper on the "Relation of Forests to Water Supplies," writing in 1892,² cites the earlier changes in the Schuylkill River: "During the last sixty or sixty-five years," he says, "this river has shown a marked diminution in its *minimum* flow. In

¹"The Influence of Forests on Climate and on Floods," a review of Professor Willis L. Moore's report, by George F. Swain, LL.D., professor of civil engineering, Harvard University, *American Forestry*, Vol. 16, pp. 224-240, April, 1910.

²Bulletin No. 7, Forestry Division, U. S. Department of Agriculture, 1893, p. 165.

of the Saco, a stream so capricious and boulder-strewn that it would be an impossibility to drive logs down it. But spruce and hemlock are exceedingly valuable nowadays, and, moreover, that Weeks bill threatens—or would threaten if it were not for that little joker—to prevent the slaughter of trees so near Mount Washington. So a lumber railroad has been driven with great energy up to the very center of this last refuge of the forest primeval."

In the Crawford Notch the cutting has been carried as far up as the Frankenstein Trestle. "The whole easterly slope of the Franconia Range and the valleys among the foothills of this range have been denuded. Indeed, from the summit of Lafayette almost all that the eye can see of the lower and western part of the Pemigewasset Valley has been swept clean and left a leafless, brown desert of slash. So from Carrigan Summit it shows on the southerly slopes of Bemis, Anderson, Lowell and Nancy."

It is evident from the above that the cutting of the forest is progressing at an unprecedented rate, and this, not merely on the lower and more gentle slopes where there is a possibility that the growth of spruce may be renewed, but also on the upper and steeper inclines where the forest, when once removed, is gone, if not forever, still at least until the next Ice Age wipes out the relics of human folly, renews the mantle of drift, and restores, after the recession of the ice, those climatic conditions which make the initiation of ever-green forests possible in such situations.

At the conference of governors, called by President Roosevelt to consider the conservation of our natural resources, after reciting the axiom: "The great natural resources supply the material basis upon which our civilization must continue to depend and upon which the perpetuity of the nation itself rests," the conference made the following unanimous declaration:

"We agree, in the light of the facts brought to our knowledge and from information received from sources which we can not doubt, that this material basis is threatened with

exhaustion. Even as each succeeding generation from the birth of the nation has performed its part in promoting the progress and development of the republic, so do we in this generation recognize it as a high duty to perform our part; and this duty in large degree lies in the adoption of measures for the conservation of the natural wealth of the country." It was further declared that "this conservation of our natural resources is a subject of transcendent importance, which should engage unremittingly the attention of the nation, the states and the people in earnest cooperation."

All of this is matter for consideration in the light of science. As abstract questions, these declarations received universal acquiescence; but diversity of opinion arises in their application, and here we enter upon a sphere of action where science and politics must combine. Distasteful as it may be to men of science to enter into the sphere of politics, the lesson which the laborers have been slowly learning, that the needs of industry receive no attention until pushed to the center of the political arena, must apparently be taken home by science also.

One of the declarations of the governors reads: "That sources of national wealth exist for the benefit of the people, and that monopoly thereof should not be tolerated." Here this honorable body touches the crux of the whole matter.

As soon as remedial legislation is attempted, the forces of monopoly show themselves to be stronger than science, stronger than governors or presidents. In fact, there is only one power that is greater—that of the people. Whenever the nation becomes so thoroughly aroused that its people act together as one man, monopoly will be overthrown. Until that time arrives, there is need for science to continue a campaign of education and to continue it *unremittingly* as the governors advise.

After the first flush of enthusiasm has cooled, look for reaction and apparent back track to make way for the next wave of advance. The need of a new movement is

already immanent. Though the campaign of education may flag, the exploiters of the nation's resources, who act without regard to ultimate consequences and for self-interest only, anxious lest their special privileges may be curtailed, are not letting the grass grow under their feet.

It becomes necessary for men of science to reiterate the fundamental facts, which they can do in the present instance with the certainty that scientific prognostications ament the passing of the forest and its resulting woes can not be made too loud or too often. The American Association for the Advancement of Science, whose memorial in 1873 was one of the beginnings of the present conservation movement, could not do a better thing than to present at its coming session another memorial to Congress, recounting the lessons which the engineers have been learning.

Professor Willis L. But the time will surely come when this policy will be recognized as a mistake.

B. E. Fernow, in a paper on the "Relation of Forests to Water Supplies," writing in 1892,² cites the earlier changes in the Schuylkill River: "During the last sixty or sixty-five years," he says, "this river has shown a marked diminution in its *minimum* flow. In

¹"The Influence of Forests on Climate and on Floods," a review of Professor Willis L. Moore's report, by George F. Swain, LL.D., professor of civil engineering, Harvard University, *American Forestry*, Vol. 16, pp. 224-240, April, 1910.

²Bulletin No. 7, Forestry Division, U. S. Department of Agriculture, 1893, p. 165.

1816 this flow was estimated at 500,000,000 gallons per day; in 1825 at 440,000,000; in 1867 at 400,000,000, and in 1874 at 245,000,000. In regard to this a commission of engineers say in their report in 1875: This remarkable decrease, not being accompanied by any great change in the rainfall, is no doubt largely due to the destruction of the forests in the drainage area, whereby the conservative action of the woodland has been lost, and the rainfall is permitted to descend rapidly to the bed and pass off in a succession of freshets."

The same bulletin (pp. 23-122) contains an elaborate "Review of Forest Meteorological Observations," by Professor Mark W. Harrington, who treats the data obtained at a considerable number of German stations by an original system of curves, bringing out the fact that the forest is cooler than the neighboring open country by several degrees. Being cooler, the dew-point is reached more quickly in the forest, when atmospheric conditions favor rain. The forest has (1) larger evaporation from widespread leafy surfaces and moist shaded soil, (2) cooler atmosphere from the local evaporation and (3) greater precipitation. Effects (1) and (3) so nearly compensate that there is hardly any difference in the total run-off from a given area, whether forested or not, but a great difference in the distribution of the flow in its annual fluctuation.

The forest question is not a meteorological problem, but one of soils, erosion and drainage. In France enormous sums of money are being expended in a toilsome effort to undo the mistakes of the past and to reforest the steep slopes. It seems strange that "eminent engineers" should not be aware of these facts, and that our country must repeat all of these unhappy blunders of older nations without profiting by their experience.

The French writer, Belgrand, quoted by Professor Swain, touches the heart of the matter when he says: "The forests diminish very notably the volume of earthy matter transported by the streams, because they prevent the erosion of the earth, and it must be

recognized that the impoverishment of the earth is much more to be deplored than the disasters caused by floods."

In the report of the chief of engineers, U. S. Army, for 1891 (p. 1107), Major Charles W. Raymond says: "The destruction of forests from the mountain crests and slopes of a watershed is undoubtedly the principal cause of the increase of the average magnitude of floods. The evidence collected during the last twenty-five years establishing this conclusion is well nigh overwhelming, and it is verified by repeated observations, not only in the mountains of Europe, but also in our own land"; and he refers to Colonel Torrelli, who "affirms as the result of careful observations that four fifths of the precipitation in forests is absorbed by the soil or detained by the surface of the ground to be gradually given up in springs and gentle rills, and only one fifth of the precipitation is delivered to the rivers rapidly enough to create floods. Upon the same slopes and surfaces denuded of their forests, the proportions are reversed. . . . That the destruction of the forests in mountainous watersheds is followed by disastrous floods where previously such floods were unknown is not a matter of theory, opinion or probability, but it is a well-established physical fact."

"In France, Italy, Germany and Austria the systematic planting of mountain slopes as a means of restoring lost fertility and preventing the inundations following the destruction of forests, is an established fact followed by results more satisfactory than the most sanguine anticipations."

The attempt to divert attention from the problem of the forest on the plea that it involves unsolved meteorological questions is an obscuring of the real question which concerns the soil. Governmental authority has been invoked ostensibly on account of increased difficulties and dangers to navigation of the rivers through neglect of their forest sources. Such perturbations of the streams do undoubtedly result from deforestation of the mountain slopes, but of far greater importance is the injury to the soil. The soil of

our native land should be even more sacred than its waters, and if necessary the constitution should be amended to enable the Congress to pass laws protecting the soil as well as the waters of our common heritage.

SCIENTIFIC BOOKS

Characteristics of Existing Glaciers. By WILLIAM HERBERT HOBBS. New York, The Macmillan Company. 1911. Pp. ix + 301.

The author tells us that the book consists of three articles, more or less amplified, which he has contributed to scientific magazines. This explains the general character of the book, which is divided into three parts; the first deals principally with glacial erosion; the second with the ice masses of the Arctic and the third with those of the Antarctic. The subject is treated in regard to some of its larger aspects, such as geographical distribution, the general forms and the meteorological relations of the ice masses. The physical character of the ice which controls its movements, the relation of reservoir to dissipator, the formation of moraines and many other details are absent, as might be expected from what has been said above. On the other hand, far more space is given to the question of erosion and to meteorological conditions than is usual in books about glaciers.

In the first part, the subject of glacial erosion, both at the bottom of the valley and in the cirque wall, is considered. Here, for the first time, accounts of Matthes's theory of nivation and Willard D. Johnson's theory of bergschrund sapping are given to the general public. The author rejects Richter's idea of sapping just above the level of the *névé*, because it would produce a broad shelf, which has not been discovered; but he accepts Johnson's theory, though this method would also produce a shelf at a level only 150 or 200 feet lower. He has, however, presented convincing evidence to show that the cirque is enlarged by sapping and that the forms with which we are familiar in glaciated mountains

are the result of the extension of cirques by glacier erosion.

There are many ways of classifying glaciers, according to the characteristics one desires to emphasize. The author classifies glaciers in accordance with the amount of alimentation, and brings out some interesting relationships of the different forms; but it seems that, in this matter, he has not put sufficient emphasis upon underlying topography.

The accounts of the Arctic and the Antarctic are particularly interesting; the author has evidently studied the reports of all the explorers and has brought them together in a very readable form and in such a way as to give an excellent general survey of those distant regions. He insists that there are very marked fundamental differences between the character of alimentation in the polar regions and in temperate zones. In the latter, the precipitation is due to moist winds being raised to cold altitudes by the mountains themselves and then precipitating their moisture in the form of snow. In the polar regions Professor Hobbs thinks that there are no surface air currents blowing across the great ice masses from the adjacent seas. It has been made out that over Greenland and over the Antarctic there are great regions of high barometer; and the reports of explorers show that they almost invariably encountered winds blowing off the surface of the ice, and when these winds attained a fair strength they carried with them many fine particles of snow which were swept along for considerable distances. These outward air currents Professor Hobbs ascribes to the cooling and consequently increased density of the air by contact with the cold surfaces, followed by the air sliding off the great ice cap in all directions. This, of course, requires that the return currents should flow in at a higher altitude, and sink down upon the ice from above. These currents, which bring but little moisture, are heated dynamically as they sink, melting and evaporating whatever ice spicules they may be carrying, and the vapor is again frozen as it approaches the ice surface. In this way he accounts for the falling snows under clear

skies, which have been described by Arctic explorers. In the Arctics there is always a fringe around the ice masses where the winter's snow is all melted during the summer. In the Antarcotics this is not the case, as the snow line extends quite to the sea level. The discussion of the various forms of ice masses and the formation and appearance of icebergs is most interesting. Glacialists will find much to interest them in this book and also many explanations with which they will not agree. For instance, the author thinks that the alimentionation of the Arctic ice occurs largely at its borders and is due to the snow being driven off the ice cap by the wind and piling up, around the edges, forming a convex surface, like a sand dune; it is hard to reconcile this with retreating glaciation. Also, the figure on page 139 would hardly have been inserted if the author had carefully considered the lines of flow of glacier ice.

The book is profusely illustrated and the illustrations elucidate the text; every one of them is referred to and they make the descriptions very vivid without the use of too many words. The reproduction, on the same scale, of plans of a number of glaciers, in plate 11, and Fig. 134, is very instructive. The numerous references at the end of every chapter will be very acceptable to those who desire to consult the original articles.

HARRY FIELDING REN

Fortschritte der Mineralogie, Kristallographie und Petrographie, herausgegeben im Auftrag der Deutschen Mineralogischen Gesellschaft, von DR. G. LINCK, Jena. Gustav Fischer, Jena, 1911. Pp. 290.

The German Mineralogical Society has undertaken to publish annually a report of progress in various fields of investigation related to mineralogy. This interesting first volume gives promise of a successful series. Dr. Linck is editor in virtue of his office as secretary of the society; the authors of the papers are specialists in their various fields and the presentation is intended to be popular. The varied subject matter shows how wide is the field to be covered. There are

twelve reports as follows. H. Baumhauer (Freiburg) treats of the Law of Complication and the Development of Crystal Faces in Complex Zones, accepting and elaborating Goldschmidt's work (17 pp.); O. Mügge (Göttingen), On the Twin Structures of Crystals (30 pp.), and F. Becke (Vienna), On the Formation of Twin Crystals (18 pp.), discuss very fully modern points of view as to definition and development of twinning; A. Ritzel (Jena) treats of the recent literature on Velocity of Crystal Growth and Solution (13 pp.). Under the heading Mineralogy, R. Marc (Jena) summarizes the literature on the Phase Rule and its Application to Mineralogical Questions (30 pp.); R. Brauns (Bonn) deals with the Causes of the Color of Faintly Colored Minerals and the Effect of Radium Rays upon the Color (12 pp.); A. Bergsät (Königsberg), reviewing the Genetic Interpretation of the North- and Middle Swedish Iron-ore Deposits in Recent Literature (18 pp.), shows the modern tendency towards regarding them as of magmatic origin; A. Schwanke (Marburg) gives a descriptive list of new minerals which have been described since 1898, arranged alphabetically without references to literature (20 pp.). Under the heading Petrography, F. Rinne (Leipzig), on Saltpetrography and Metallography in the Service of the Study of Eruptive Rocks (37 pp.), shows the bearing of such physico-chemical investigations as those of van't Hoff on the Stassfurt salt deposits upon the interpretation of processes of crystallization in igneous magmas; F. Becke (Vienna), in *Advances in the Province of Metamorphism* (36 pp.), reviews 87 papers which have dealt with this subject in the past three years. Under Meteorites, F. Berwerth (Vienna), *Advances in the Knowledge of Meteorites since 1900* (28 pp.), gives a complete bibliography of 394 entries, covering what has appeared on meteorites since the publication of Wülfing's book, together with critical reviews of many papers. Lastly H. E. Boeke (Halle) gives a brief account of the work of van't Hoff, especially as it bears upon mineralogy and geology.

The book is sent free to members of the society and is also on sale through dealers.

C. PALACHE

Nature Sketches in Temperate America. By JOSEPH LANE HANCOCK. Chicago: A. C. McClurg & Co. 1911. Pp. xvii + 451, 12 col. pls., 215 figs.

The preface of this attractive book says that it is a "popular exposition of the facts gleaned from nature" which often presents the subject "from the artistic or æsthetic point of view. This method does not sacrifice truth, which is the religion of science, but mitigates it, bringing about a wider reading circle. . . . More consideration is given to insects than to other groups of animals" and "the relation of animals and plants to their natural surroundings has been kept constantly in mind." The bearing of the subject matter on the theory of evolution is also considered in some detail.

Chapter 1 is devoted to "Evolution and Natural Selection." It gives a brief but complete discussion of the most generally accepted ideas concerning evolution and heredity with a few notes concerning their bearing on the subjects under consideration. Chapter 2 takes up "Adaptations in Plants and Animals, with Examples" and presents some interesting cases of particular adaptations—such as: how the milkweed profits by the visits of its insect guests; bird flowers; and the seasonal procession of flowers, insects and birds. Chapter 3 begins with a brief discussion of the theories of protective resemblance; the tree toad is next described, and the writer then takes up the walking-stick and various other insects and insect larvæ that are protected by their form, color or behavior. Chapter 4 is devoted to mimicry, and after discussing Bates's, Müller's and other theories, describes the monarch and viceroy butterflies, a bumble-bee and a robber-fly, and flower-frequenting flies. Chapter 5 takes up Wallace's theory of warning colors and then passes to a consideration of several bright colored lepidoptera and lepidopterous larvæ. Under the title "Animal Behavior, with Examples,"

Chapter 6 is opened with a brief statement of the author's ideas on instinct and intelligence and a table showing the distribution of sense organs in insects; then follow brief descriptions of the habits of many insects, spiders and birds. Chapter 7 is devoted to "General Observations and Sketches Afield." It considers: the formulation of problems, origin by adaptation in nature, ponds, brooks, meadows, the bumble-bees' night camp, etc. The title of Chapter 8 is "Ecology—Interpretation of Environment as Exemplified in the Orthoptera." In it are discussed the sources of life after glaciation, habitats of plants and animals, zoogeography, nature's reclamation of sterile ground, and various things concerning a number of Orthoptera. The last chapter consists of two parts: (1) a "classified list of habits of various species of Orthoptera based on their egg-laying sites, to show their relation to plant formations in general" (which follows the classifications used by some plant ecologists) and (2) "definitions of common environmental complexes, grouped under formations," in which seventy-six terms (including ocean, sea, lake, pond, pool, stagnant water, snow, alkali, sterile and man's houses) are defined.

The book contains many interesting descriptions of the habits of animals. Among the best of these the parts of chapters on the habits of the walking-stick, the castle-building spider, the golden SpheX as the grasshopper's enemy and the habits of the green meadow grasshopper, may be mentioned. An excellent picture is presented of the life of the animals discussed. The colored plates are excellent, and the same is true of many of the photographic plate illustrations, but some of the latter are so dark that they fail to show the points they are intended to demonstrate.

Hancock presents the theories of natural selection, mimicry and warning coloration in a rather dogmatic fashion and follows them with examples which have not always been indubitably proven to have been brought about in the way he intimates. A reader unfamiliar with the field might easily believe that these dogmas had never been disputed,

for the theories and examples are presented with little comment and the writer is "satisfied to let the reader draw his own conclusions." With what Hancock gives, the reader would doubtless conclude that everything was readily explained by the theories presented—though by this method the theories have the advantage of being clearly and definitely formulated. The reader is rather disappointed when he finds that the hundred-page chapter headed "Ecology—Interpretation of Environment as Exemplified in the Orthoptera" consists mostly of short descriptions of the habits of grasshoppers, and he looks in vain for the "interpretation."

The general reader will probably be confused where such terms as lores, calamus, rachis, vanes, barbs, barbules (p. 46) and luna (p. 60) are introduced without explanation. There is frequent and somewhat monotonous allusion to a "plate photographic illustration" which is often several pages from the reference. The reader would have been saved much time by a page reference. At the top of page 384 reference is made to a plate that appeared in the *American Naturalist* in 1905 but does not appear in the book! Among other loose and careless statements, such as are likely to appear in any first edition, the following may be mentioned: Humming birds are said to occur "in the tropics" and they are found only in America (p. 43). On pages 73 and 75 "this species" is discussed when no species has been mentioned; on page 86 the pronoun "them" refers to "substance." The following sentence occurs on page 299: "The cherries were luciously ripe, and after eating a few, one is apt to feel a dislike for their pungent flavor." "Geophilous" is used to designate animals that feed on the surface of the ground (p. 356), and one wonders how an animal like the earthworm, that eats dirt, would be classified. These definitions are given (pp. 432 and 433): "Desert: Vast sandy tracts of land, appearing in western United States, where evaporation exceeds rainfall. . . . Man's Houses: Country and City Houses; (a) basement; (b) upper floor."

Rana catesbiana appears on page 800 as *R. catibiana* and on the plate facing this page as *R. catibiani*. It is difficult to understand the writer's meaning when (p. 356), after stating that short-winged acridians are less numerous in treeless, arid districts than in humid, forested regions and that most flightless species of locusts are plant-feeding as distinguished from ground-feeding, he says: "My own conclusions . . . is simply this: that it is a question of food supply and nutrition derived therefrom. In the case of short-winged forms, they are due to under-development as the result of scant food."

A. S. PEARSE

SPECIAL ARTICLES

ON POWERS OF TEN

FOR expressing numerically the widely varying magnitudes occurring in scientific work, two methods are in common use. Both are adequate and accurate, but results expressed by means of one are much more easily grasped and remembered than with the other. The more convenient method appears to be gaining in use. The present paper is written with the idea that this desirable change may be accelerated if the advantages of the method are stated, and thus presented to those who have hitherto not given the matter special attention.

The simplest way of writing a number is, of course, to write it out in Arabic notation. But this, in general, involves the presence of numerous ciphers, which the reader must count in order to learn what the number is. There is, therefore, a gain if the writer counts the ciphers for him and records the number obtained. Hence the familiar system, where a number is given as the product of (1) a series of significant digits, and (2) ten, with an exponent (e. g., the velocity of light is 3×10^{10} cm. per sec.).

This system has still one great disadvantage: it calls in each case for the reading of two numbers, and thus greatly increases the strain on both the attention and the memory. And this difficulty is multiplied when the

quantity expressed is less than unity, as it is about half the time. For then the exponent is negative, and the two numbers affect the resultant magnitude in opposite ways.

For instance, suppose a galvanometer which requires 3×10^{-8} amperes to give unit deflections: how will its sensitiveness compare with that of one for which both indicating numbers are numerically larger, say, 8.0×10^{-9} amperes? The larger significant figure, 8.0, indicates a larger current, and therefore less sensitiveness, but the exponent, 9, though also larger, indicates greater sensitiveness. Really, the second is about four times as sensitive as the first, but this fact is far from evident on a first reading; yet this is a very simple case. If a reader should see an account of one of these instruments on a Friday, and of the other on, say, the next Wednesday, it would require unusually careful reading indeed to leave him with any definite idea of the relative sensitiveness.

The difficulty of this system can also be well stated as follows: When a number of magnitudes, say diameters of small rods, is stated, sometimes in centimeters and sometimes in millimeters, it is evident that a good deal of unnecessary difficulty results, which can be avoided by sticking to one unit or the other. Now, between a millimeter and a centimeter there is the same difference as between any two consecutive powers of ten. An unrestricted system of notation by powers of ten, therefore, amounts practically to an unnecessary multiplication of the number of working units.

The remedy is obvious—to diminish the number of units. This is realized in the other system, which proceeds by steps of 1,000, instead of 10. A further gain is sometimes secured by using prefixes instead of exponents to indicate the working units, since the combination of a word and a number is preferable to two numbers, each of which interferes with the apprehension of the other, and even more with its recollection. This system is perhaps seen at its best in the field of electricity, where, besides the units, ampere, ohm, volt,

etc., the milliamper, millivolt, microampere, microvolt, kilowatt, megohm, etc., are in common use, and have almost completely displaced the reckoning by powers of ten. The advantages of the system have been made available in stating galvanometer sensitiveness by the scheme proposed by Ayrton. The sensitiveness is simply put equal to the deflection produced by a unit current, usually the microampere. According to this scheme, the sensitiveness of one of the galvanometers mentioned above is 125, of the other, 33. Here the difficulty of remembering or comparing the two quantities would seem to be reduced to the minimum. And this illustration gives a fair idea of the value of the general method. Under it, but one thing claims attention: a single number, which need never exceed 3 digits unless the accuracy attained calls for a larger number of significant figures. Such a number is relatively easy to comprehend and to remember. The unit needs almost no attention, since all magnitudes between which a comparison is likely to be desirable will be expressed either in the same unit, or else in units so far apart that no confusion will occur.

This choice of units is, of course, the essential part of the method, and it, of course, can be realized under the form of the notation by powers of ten by those to whom that form seems desirable. All that is necessary is that those powers of ten shall be chosen which are also powers of 1,000, so that the use of 10^3 , 10^6 , 10^9 , 10^{12} , etc., is to be discontinued. But the use of the prefixes to denote the units seems decidedly preferable. The electrician who should be advised to abandon his microvolts and milliamperes, and go back to "volts $\times 10^{-6}$," etc., would scarcely be profoundly impressed with the value of the advice.

A few special points seem worth noticing in this connection.

A single prefix to denote 10^{-9} seems desirable. Until it appears, 10^{-9} amperes (for instance) should of course be called a millimicroampere. "Micro-micro," of course, means a millionth of a millionth, or 10^{-12} , and is illogical when used for 10^{-9} , besides

being less euphonious than the other. But it may be too late to stop the illogical use of $\mu\mu$ for the millimicron ($m\mu$) in the domain of optics.

There will undoubtedly be a tendency, as reckoning by powers of 1,000 comes more into use, for work in each particular line to be always expressed in the same derived unit. Here the advantage of a common unit more than compensates for the fact that in some particular cases the unit is not quite the most convenient. For instance, workers with thermoelements have generally found it advantageous to work in microvolts, and to keep to this unit even when the number of microvolts is over 10,000, that is, more than 10 millivolts.

In case of doubt between two units, it is probably better to use the smaller. For this diminishes the use of fractions, and also gives records more likely to be concordant with future work, since the increase of accuracy as time goes on increases the advantage of the lower unit.

In no class of quantities is more to be gained by reckoning by powers of 1,000 than with coefficients of expansion, and temperature and pressure coefficients generally. If these quantities were always tabulated in thousandths or millionths, instead of with a variable number of zeros, according to the fancy or convenience of the tabulator, a very much larger number of them would actually lie in the memory of the average working experimenter than are now to be found there. Yet these quantities, and some others, being pure numbers, have no special name, and therefore nothing to which the prefixes, milli-, micro-, etc., can be attached. They may legitimately be designated as "parts per mille," "parts per million," etc., but these expressions are rather awkward, particularly when the whole expression is "parts per mille per degree," or something like that. It would be convenient to use the fractional prefixes alone as nouns in such cases, milli meaning one part per thousand, and micro, one part per million. There is certainly considerable reason to wish that some leader, or committee, having sufficient

authority, would authorize the use in this way of these terms (or something better). They have these advantages: They are brief; they would harmonize with the terms used for other physical quantities; they would tend to extend the use of powers of 1,000. For instance, at present, most observers, working to an accuracy of (say) 10 parts per million, would prefer to state it as one part per 100,000, while with the word "micro" in use the almost universal expression would be 10 micros. And the use of powers of 1,000 is quite as desirable in stating errors, etc., as in most other cases.

The use of fractional or multiple prefixes also sounds a little strange in those cases where, in order to adhere strictly to the C.G.S. system, the centimeter is used as the unit of all linear measurements. The real difficulty here, however, does not lie in the prefixes, but in the fact that two different fundamental units, the meter and centimeter, are in use, and that most physicists are probably more used to measuring small lengths in millimeters and microns. This difficulty would not be increased by the use of the term millicentimeter and microcentimeter, which are of course the logical terms to use if the centimeter is to become the practical unit of all lengths. It also seems logical to use the centimeter only where such other C.G.S. units as the absolute electrostatic and electromagnetic units would be used, and to use the millimeter and micron in cases corresponding to those where the ampere, ohm and volt would be considered appropriate.

In any case, it may be well to repeat, the main and essential advantage of the newer system that is coming into use is in the restriction of notation to powers of ten which are also powers of 1,000. And this restriction can profitably be adopted whatever may be thought or done regarding the other points mentioned in this paper.

THE attention of the section was directed to aeronautics as long ago as 1886, when my distinguished predecessor, Octave Chanute, in his address at Buffalo, mentioned the possibilities of aerial navigation, a subject which entirely absorbed his later years and which he lived to see completely realized. Again in 1904, Professor C. M. Woodward devoted a portion of his vice-presidential address at Philadelphia to a consideration of the navigation of the air, which at that time had been accomplished with dirigible balloons. Papers on aeronautical subjects, or relating thereto, have been presented in increasing numbers to the section, reaching a maximum of eleven in 1909. Last year, the writer, as chairman of the section, made a special effort to secure such papers through a preliminary circular, thus worded:

The rapid advance in the navigation of the air during the past year has attracted serious attention to scientific aeronautics. The construction of dirigible balloons and flying machines is essentially a mechanical problem and as such merits consideration by this section, especially since no engineering society has yet taken this action. Accordingly papers are invited relating to aerodynamics and other branches of aeronautics and also discussing possible courses of instruction in colleges and technical schools.

As a result ten papers were presented and an aeronautical curriculum was for the first time discussed here.

The subject of this address, "Aerial

¹MSS. intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹Address of the vice-president and chairman of Section D—Mechanical Science and Engineering. Washington, 1911.

Engineering," suggests a new field for the profession, analogous to marine engineering and which may in the future prove almost as important. So long as the spherical balloon was the sole method of rising in the air, the technical questions involved belonged to physics and chemistry rather than to engineering, but with the advent of the dirigible balloon and the aeroplane, the mechanical engineer was called upon to provide the lightest possible motive-power and to design the framework of the balloon and the supporting surface of the aeroplane to sustain the greatest stresses with the least weight.

The determination of the meteorological conditions at different heights and places and under all weather conditions belongs to the meteorologist and his observations originally made in the interest of pure science now become of practical value. The necessity of knowing the conditions which may be encountered by air-craft in their voyages through space of three dimensions will ultimately lead to the construction of flying charts at different levels but otherwise similar to the sailing charts for the ocean. A beginning has already been made by the writer, who has published a series of twenty-four charts based on material collected by the Blue Hill Observatory in the United States and over the Atlantic Ocean. Since in the air as on the earth it is not the average, but the individual thing, which happens, an attempt is made to specialize for the time of day and season and also to show the sequence of wind-changes aloft which accompany different barometric conditions at the ground. A knowledge of the wind, which varies with both place and level and depends upon the meteorological situation, has a far greater importance for the airman than for the navigator, whose vessel rests on a dense and relatively stationary

medium. In general, the velocity of the wind increases with height and its direction becomes more constant, but the observations at Blue Hill seem to indicate that the gusts of wind, while increasing with the average velocity, decrease as we rise in the free air and are greatest near the ground in northwest winds, where they may be double the average speed. In experiments there by Mr. S. P. Fergusson, as many as ten pulsations per second were recorded by the most sensitive anemometers on a wide time-sheet. The uprush of air under cumulus clouds, which are especially strong when they become cumulo-nimbus or thunder-clouds, are dangerous to all aircraft that depend on dynamic equilibrium, as are the eddies termed by aviators "holes in the air," which are produced by superposed currents having different velocities or directions. It is possible for an aeroplane to fall when traveling with the wind if the gust greatly outstrips the mean velocity of the current that carries the aeroplane, which our experiments show to be a frequent occurrence, because its relative motion through the air, due to its motor, and therefore the upward component which furnishes support, is decreased by the inertia of the flying-machine preventing it from responding to the sudden impulse. The same thing may happen when going against the wind if a sudden lull occur, and if the aeroplane pass abruptly up or down into another air stratum of different velocity. Such local currents and atmospheric eddies, which have long been known to meteorologists from the behavior of their kites and balloons, will now be studied *in situ* and with danger by the aviator. Some of these disturbances may be counteracted by automatic control of equilibrium, but generally by increasing the speed and size of the machine and so rendering it less susceptible to the influence of those per-

turbations of the atmosphere which are of limited extent and duration. To-day the most needed improvements in aeroplanes are stability in wind-eddies and safety in landing.

The meteorological phenomena causing these difficulties are discussed here at some length because their solution belongs to mechanical science and therefore merits the attention of our best engineers. There is an erroneous idea that the aeroplane has been developed without laboratory experiments and that a study of the theory of flight, and hence the science of aviation, does not require theoretical knowledge of the different factors which influence it. The pioneers in aviation, Lillienthal, Maxim, Langley and the Wrights, experimented in the laboratory with surfaces exposed in wind-tunnels and on whirling-tables, and the best shapes for balloon-envelopes to present the minimum resistance to propulsion were also obtained from models. Theoretical knowledge based on experiments is indispensable to the aeronautical engineer as distinguished from the aviator. Only on such a foundation can we build up the new science of aeronautics and a technology which is indispensable for the development of this new branch of engineering.

M. Eiffel, the distinguished engineer, in describing the results of his recent work in aerodynamics says:

It must be admitted that the experiments in the laboratory with small models can furnish data useful to aeronautical constructors, saving them both money and time in experimenting. For a series of laboratory experiments made on model aeroplanes, or on wings of small size, which can be quickly and surely modified, gives the basis for later computation, either for the section of the different members depending on the strength of the material used, or for the conditions of equilibrium and stability, having regard to the calculated or assumed weight for each member. The same thing applies to a model of a screw-propeller

which tried under proper conditions may give information about the action of the actual propeller. The experiments with full-sized aeroplanes are almost always disturbed by wind, which introduces very large causes of error, and the trials being made necessarily with new apparatus of uncertain operation are generally dangerous. On the other hand, laboratory experiments can be conducted at any time and under different conditions and their results enable the knowledge of the engineer to replace the inspiration of the constructor, which in new fields may sometimes lead to fortunate discoveries, but may also give rise to costly mistakes.

The establishment of aerodynamical laboratories, therefore, marks the entrance of aeronautics into the domain of engineering. Probably the first of these was organized by Captain, later Colonel, Charles Renard at the Central Establishment for Military Aeronautics at Chalais-Meudon, near Paris, about 1884. Here important investigations on light motors and the resistance of bodies of different shapes to motion through the air were conducted, which resulted in the first successful dirigible balloon, *La France*. Experiments upon lifting screw-propellers, with a view to aviation, followed, and Colonel Renard carried on similar work until 1903, when he was succeeded by other officers and the name of the laboratory changed.

Important experiments on the resistance of the air to falling bodies were made between 1903 and 1906 by the eminent constructor of the Eiffel Tower there and later at his laboratory provided with a large wind-chamber on the Champs de Mars. Of great importance are the determination of the relations between the velocity and pressure of the air on a normal plane and upon plane and other surfaces at varying angles of incidence, the distribution of the pressure over the surface and the tests of aeroplane-wings. The results of the experiments have been published in two large volumes with the detail and elegance characteristic of M. Eiffel.

Another experimental establishment of wider scope has recently been created in France through the generosity of a patron of aeronautics, M. Deutsch de la Meurthe. This is the Aerotechnical Institute of the University of Paris, located at Saint Cyr, near the Buc aerodrome and the Satory camp, the center of military aeronautics in France. It is planned to study all theoretical and practical problems of aviation and aerostation relative to the support of bodies in the air, both at rest and in motion. The institute is primarily a testing establishment where constructors and experimenters may bring aeroplanes, or their parts, to be tested by the best devices at actual cost; and secondarily it is an institution where aerodynamics is studied in theory and in practise by experts for the government and some of the results are published as an aid to the science. The invested capital is \$100,000 and an additional annual income of \$3,000 is provided by M. Deutsch. The director of the institute is Professor Maurain, who has an advisory committee composed of eminent French scientific and aeronautical experts, including representatives of the University of Paris and the Aero-Club of France and government officials.

An earlier laboratory of the same nature in Russia was the Aerodynamic Institute of Koutchino, founded in 1904 by M. Riabouchinski in connection with the University of Moscow. Its object is to investigate problems of pure and applied aerodynamics, general aeronautics and meteorology and three volumes containing results of the valuable investigations have been published. The initial cost of the plant was about \$77,000 and the proprietor further donates some \$27,000 a year for the researches.

An aerodynamical laboratory was established at Göttingen, Germany, in 1908,

through the initiative of the Society for the Study of Motor Air-ships, aided by the Göttingen Technical Association, the government and the Krupp gun-firm, the laboratory receiving in the aggregate more than \$7,000 a year. Professor Prandtl, who also holds the chair of aeronautics in the University of Göttingen, is director of the laboratory, and has as advisers Germans prominent in physics and engineering. In Austria there are at least two private experimental laboratories.

The National Physical Laboratory at Bushy Park, near London, now has an aerodynamical department with an advisory board composed of men eminent in different branches of science, Lord Rayleigh being the chairman, who are appointed by the prime minister. The experimental apparatus for investigating general questions in aerodynamics includes a wind-tunnel, a whirling-table, two wind-towers for experiments in the natural wind, a motor-plant and arrangements for testing the permeability of balloon and aeroplane fabrics and the strength of light alloys for construction. A report of the advisory committee for 1909-10 has been published as a government blue book.

There is a well-equipped laboratory in Italy for the military aeronauts and in other European countries similar establishments exist, the work of which is not disclosed.

From this rapid survey of the principal scientific establishments for the study of aeronautics in Europe, it will be seen that they may be divided into two classes: first, those privately endowed laboratories, which are either personal or connected with some institution but whose object is the advancement of the science and practise of aeronautics; and second, those supported by the government for military

purposes, but which may publish data of value to constructors and students.

Instruction in aeronautics is now given in many foreign technical schools and universities, the best known course of study being under Professor Prandtl at the University of Göttingen, in connection with the laboratory already mentioned. M. Basil Zaharon, a wealthy Greek residing in Paris, has endowed a chair of aeronautics at the Sorbonne with a fund of \$140,000, so that France will soon rival Germany in facilities for training students in this science.

The United States is almost absolutely lacking to-day in aeronautical laboratories and technical instruction, for the brilliant researches in the past of Langley, Zahm and Nipher have not been followed by similar work since the flying machine was realized. Our government maintains no aerodynamic laboratory and few of our technical schools or colleges possess apparatus for this purpose, while none offer regular instruction though some investigations have been made by advanced students. The instruction in flying by the so-called aviation schools is, of course, unworthy of consideration, since the best of these only teach the aviator to operate and repair his machine as the automobile school does the chauffeur.

It appears likely that the demand for collegiate instruction from young men wishing to enter aerial engineering as a profession will soon require the establishment of regular courses of study based on the European curriculum, at the completion of which a degree or certificate of proficiency shall be given, ranking with that conferred in other professional courses. It seems to the writer that aerial engineering can best be taught in institutions that now possess departments of mechanical engineering and naval archi-

tecture, for the preliminary training would be the same as that now given in these studies and the specialization would consist in the substitution of air for water as the navigable medium. The installation of laboratories having powerful blowers connected with large wind-tunnels, or equipped with whirling-tables in a large enclosed space, is, of course, essential.

The board of governors of the Aero Club of America have requested the committee on aerodynamics to consider the most feasible method of organizing and maintaining an aeronautical laboratory in this country. This committee, of which the writer is a member, through its chairman, Dr. A. F. Zahm, has made a preliminary report containing the following suggestions. The fact that the United States Signal Corps and the Bureau of Navigation of the Navy Department will probably establish such laboratories for their officers, should not prevent the creation of a civil aeronautical institution similar to those already described in England, Germany and Russia. If the English precedent is followed, and the laboratory be maintained by the government, it could properly be attached to the Bureau of Standards, but if privately endowed, like those on the continent of Europe, it might become an adjunct of the Smithsonian Institution, and this would be the more appropriate because the institution through its late secretary has already undertaken extensive aerodynamical researches and still possesses workshops and a special library.

Two years ago our chairman, Professor G. F. Swain, in speaking of engineering as a profession, remarked that aeronautics was a peculiarly appropriate field for this section to occupy, because it had not been taken up to a considerable extent by the engineering societies. This is still true to-day and the object of this address is to

convince the members of this section and of our engineering societies of the importance of establishing aeronautical laboratories and courses of instruction in aerial engineering in America, in order to keep pace with their rapid development in Europe. The fundamental researches of our late associates, Langley, the physicist, and Chanute, the engineer, which first demonstrated the principles of dynamic flight, should be an incentive to further scientific work in this country towards its perfection.

A. LAWRENCE ROTCH

BLUE HILL METEOROLOGICAL OBSERVATORY,
HYDE PARK, MASS.

THE INDEPENDENCE OF THE CULTURE OF THE AMERICAN INDIAN¹

IF one considers for a moment a map of the world, the two American continents are seen to possess one obvious characteristic in which the other great land masses do not share—isolation. From the time of the discovery America has been known as the new world, and indeed the name seems well deserved. Europe, Africa and Asia together with Australia and most of the islands of the Pacific form a closely connected and nearly continuous area. Within its limits races have come and gone, civilizations and cultures have risen and passed away, but each has been to some extent directly or indirectly influenced by others, and strong cultures have made their effects felt, albeit but faintly sometimes, to the furthest limits of this old world. A Mongol chieftain once made all Europe tremble; the conquests of a Chinese king perhaps decreed the age-long wanderings of the Polynesians; and the visions of an Arabian epileptic were the cause of movements that have overthrown empires and profoundly influenced the life of men from

¹ Address of the vice-president and chairman of Section II, Washington, 1911.

the northern rim of Europe to the edge of the South African deserts, and from the Pillars of Hercules to the Spice Islands of the east.

To understand and analyze, therefore, the culture of any given people or portion of the old world, the possible far-reaching effects of other cultures even although remote, must be borne in mind. In this it would seem, however, that America might be excepted. As far back at least as history or tradition goes it has stood alone, touching that other and older world only in the frozen north, and when, at the time of the discovery, Spanish, French and English broke down its barriers of isolation, it was to reveal peoples and cultures which for centuries and perhaps millenniums had been developing their own civilizations apparently untouched, neither influencing nor being influenced by those of the old world.

Yet in spite of the apparent isolation in which the people of America lived, no sooner were they known than various general similarities between them and peoples of the old world were observed, and theory after theory was brought forward attempting to derive them or their culture *en bloc* from elsewhere. Some, mostly of the earlier period, looked to the Semites and the Lost Ten Tribes, others to China and a party of Buddhist monks; others still to the islands of the South Seas or to Egypt and the fabled Atlantis. All such theories, however, it need hardly be said, belong to the period before the present in which more accurate and abundant observation and careful scientific method are employed. In spite of the many such theories exploited, the majority of students refused to accept the conclusions, many indeed going to the opposite extreme. They admitted that the various cultures which, as a result of the activity of investigators, had been

gradually outlined in the two Americas had unquestionably influenced one another, but they felt that although all American cultures might thus be in some degree interrelated, they had had no connection with any of the cultures of the old world. The similarities observed were thought to be coincidences due to the effects of similar environment and to the fundamental unity of the human mind. In short, so far as the history of culture was concerned, the new and old worlds formed two closed circles, tangent but not intersecting, within each of which different cultures had modified each other, but between which little or no interaction had taken place since human culture had attained to any real differentiation.

As our knowledge of different cultures both in America and elsewhere has come to be more detailed and their historical relations have become more and more apparent; as the methods of investigation have grown more exact and the criteria of relationship become more defined, the feeling has grown that after all, perhaps, the similarities between old and new world cultures might have a deeper meaning.

I may be permitted perhaps at this point to outline very briefly some of the methods and what seem to me to be some of the most reliable criteria of this so-called historical as opposed to the evolutionary school of anthropology. Such statements must indeed be trite, but will make clearer perhaps my argument further on. In essence the method depends upon the realization of the complexity of culture, that that of any given people is probably made up of elements derived from many sources, and that analysis must therefore precede a clear understanding. The analysis completed, the separate elements must be traced step by step and from tribe to tribe to determine their distribution. This

necessarily involves much careful consideration of apparently insignificant details, close comparison of archeological material with modern forms, the sifting and weighing of historical traditions, and the searching analysis of dialectic and archaic forms of speech. If as a result of such study, similarities are found to exist between different tribes or peoples, this is regarded as evidence of a real historic relationship; either one tribe has borrowed directly or indirectly from the other, or both have felt the influence from a common source.

But in drawing such conclusions we must proceed with caution, and constantly test our conclusions by reference to certain general principles. Perhaps the most obvious of these is the possibility or probability of such relationship on geographic or historical grounds. Thus resemblances between one tribe in South Africa and another in Chile would afford little basis for assuming relationship in their cultures, as from their very wide separation and known history, no reasonable ground exists for assuming any possible connection. On the other hand, similarities between the people on a remote island in eastern Polynesia and others in Assam or southern China may be significant, as there exists a possible route by which cultural influences or even migrations might have taken place, and there is historical evidence of movements of population on a tremendous scale in just this direction.

Another factor of importance is that of continuity of distribution. If striking similarities are observed between two widely separated peoples and no trace appears, either among the living peoples intervening, or from archeological evidence, of any connecting links, and there is no evidence of migrations, we must be cautious in assuming any genetic or historical relationship, and adopt at least as a work-

ing hypothesis that the similarities are due perhaps to convergent evolution, and that the two phenomena are in origin independent. A third point must also be considered in this connection. In tracing cultural influences and relationships, especially over wide areas, it is not to be expected that the implement, custom or belief will remain throughout precisely the same. As we pass from tribe to tribe and from region to region modifications are almost certain to be made, either in accordance with the various tribal or national characteristics and inherited tendencies, or as a result of the varying environment under which the people live; the implement will vary as a result of new uses and materials, the custom or belief will change with the different habit of thought and attitude toward the world of different tribes.

Of great importance again in drawing inferences from the observed similarity between implements or customs in different areas is the character and relative complexity of the things between which the similarity exists. Thus that two widely separated peoples both make use of a simple dug-out canoe is no necessary indication of historical or genetic relationship between them, as this is one of the simplest forms of canoe possible, and one which any two peoples making use of wood as a material must almost inevitably hit upon. If, on the other hand, both peoples make use of a canoe of unusual shape or one which shows some peculiar technical features in its construction or ornamentation, then the possibility or probability of relationship between the two peoples is established and should the peculiarity moreover be known only among these two peoples the evidence would become all the stronger. Further, if the peculiarities are in one case dependent on and in close relation to the environment or necessitated by

it, and in the other they show no such relation or are present only as useless or even detrimental features, the probability that the latter has in some way been derived from the former becomes great. The validity of the evidence for historical or genetic relationship thus is directly proportional to the unusualness or complexity of the things compared, features of very wide distribution or of very simple character being almost worthless for purposes of argument.

Lastly, if an attempt is made not merely to show relationship between single implements, customs or beliefs among different peoples, but to demonstrate a similar relation for an entire group of cultural elements, consideration should be given both to the question of the relative permanence and resistance to change of the different elements separately, and to the relative importance in the respective areas of the group of elements on whose similarities the claim for general cultural relationship is based.

The historical method in anthropological investigation, then, if it is to lead to trustworthy results, requires on the part of the student not only most careful and minute investigation and comparison of the facts themselves, but also the constant consideration of these in the light of their relation in time and space, their continuity, their modifications, their individual character and their relationship to the sum total of the culture of the respective peoples. That enthusiastic adherents of or converts to this historical as opposed to the evolutionary school should be led away by their enthusiasm and in so doing neglect to give due weight to these considerations is natural. It is also natural that the conclusions so arrived at should often be striking and almost revolutionary. But although the results may not receive gen-

eral acceptance, and although the theories may even bear upon their face their own refutation, still they may serve a useful purpose. On the one hand they may exemplify the dangers to which the followers of the historical method are exposed, and on the other they may often direct attention to a group of facts whose significance has been overlooked.

Such an over-enthusiastic application of the historical method as regards the question of the independence of the culture of the American Indian is exemplified to my mind in the theory recently advanced of the real and fundamental relationship of American and Melanesian cultures; I refer to that put forward by Dr. Graebner in his "Die melanesischen Bogenkultur und Verwandtes." The conclusions reached by the author of this most striking and painstaking study are, it seems to me, of value in demonstrating both the strength and the weakness of the method. For the ethnology of Melanesia, Polynesia, Micronesia, Indonesia and Australia, together with the adjacent parts of south-eastern Asia, Dr. Graebner's work is, I believe, in large measure valuable. It is where, abandoning the comparatively firm ground of Oceanic ethnology in which he is at home, he looks further afield, and finds in America (as indeed also in Asia, Africa and Europe) the evidences of a specific Melanesian culture, that I believe we must hesitate to follow him, and subject his facts and conclusions to careful scrutiny. General principles may often best be illustrated by concrete examples, and it is therefore with the idea of exemplifying some of the principles previously laid down, and not in any spirit of unfriendly criticism, that I propose to analyze and examine that portion of the theory of the Melanesian bow-culture which relates to America.

The theory in general may be summed up as follows. By a detailed analysis of the rather bewildering culture complexes of the closely interrelated peoples of Oceania, the conclusion is reached that a number of distinct cultures may be recognized, each marked by a coherent group of characteristic implements, usages, forms of social organization and beliefs; that these several cultures have spread successively over the region in question, and by their varied intermixture and superposition have produced the great complexity we find to-day. The various elements which go to make up the different cultures are regarded as so intimately interrelated and combined as to be practically inseparable, and as a particular combination to have had a definite origin in time and space. The occurrence of any considerable number of the separate elements of such a group among any given tribe or people is considered as sufficient evidence of the existence of the whole culture complex as an integral and historical feature in its development.

Of the various cultures so outlined and traced throughout Oceania, that of the so-called Melanesian bow-culture is taken up in most detail. The distinguishing characteristics of this culture are described as the self-bow of flat cross-section, arrows with fore-shafts, pile-dwellings, coiled pottery, twilled basketry, spoons, the hammock, paddles with handles at right angles to the shaft, bamboo combs, suspension bridges, the use of betel and tobacco and the pipe, hour-glass drums, communal dwellings, head-hunting and associated skull-cults, and the use of the squatting human figure and the spiral in art and design. Associated always closely with this culture is the two-class matriarchal culture, whose distinguishing features are in part the rectangular house with gable-roof,

plank-canoe, secret societies, masked dances and ancestral cults. Dismissing for the purposes of this enquiry the validity of these groups, and the correctness of the conclusions drawn in regard to their distribution in the Oceanic area, let us very briefly consider the evidence brought forward to prove their presence as fundamental and integral parts of American culture.

Beginning with North America, we find it stated that except for a few forms in the western United States which are of the type of the self-bow with flat cross-section, all other bows north of Mexico are either derivatives of the composite Asiatic or the reflexed, strengthened Arctic bow. Incidentally it may be noted that the statement could hardly have been more incorrect, as with few exceptions it is precisely in the west and on the Pacific coast that the strengthened bow is common, whereas the self-bow of rectangular cross-section is for the greater part of the eastern portion of the country the prevailing type. The presence, however, of the self-bow in North America is given as the first argument for the existence here of the Melanesian culture. It is to be noted, however, that this type of bow is almost the simplest and least elaborated form possible, the only simpler form being that where the stick has been left round in its natural state. Therefore the fact that this simple form of bow, which is in other parts of the world widely distributed, occurs both in America and in Melanesia does not constitute evidence of any historical relation between the two cultures.

For the Melanesian bow-culture in Melanesia, pile-dwellings are given as one of the most important characteristics, and their presence in America is signaled in Florida and on the northwest coast. So far as the first case is concerned, the rather

obvious relationship to similar types in northern South America, and the known Antillean and South American influences which have affected the Floridian peninsula and the adjacent parts of the Gulf shores, are wholly ignored; and to regard the occasional instances of the use of wooden blocks a few inches in height under the foundations of northwest coast houses as traces of pile-dwellings seems to strain the theory of historical relationship to the breaking-point. Pottery of coiled technique is referred to as another link connecting Melanesia and America, but here again little importance can be given to resemblances in such a simple factor, for the coil process is one of the most common methods employed in pottery-making by people the world over where the potter's wheel is not known. Twilled basketry is attributed to the Pueblo and Muskogean tribes, but its possible historical connection in the latter case at least, with Antillean and South American types, and its partial dependence on material, are both overlooked. The use of spoons which, contrary to the author's statements, is very widespread in North America, is a further striking example of an extremely simple implement, not whose peculiar form or decoration, but whose mere existence is regarded as evidence of cultural relation. Similarly without real value and in part erroneous as to fact, are the references to the paddle with handle at right angles to the shaft, and to communal dwellings. Since paddle shafts must either end in some form of cross-handle or be, like a broom-handle, without the cross-grip; and since dwellings must be either communal or not communal, there being no *tertium quid*, it hardly seems that the presence of one of the only two possible forms in each case should be regarded as evidence of cultural influence or identity.

On the basis of facts such as these which have been given as examples, and without further study or investigation of American cultures themselves, it is assumed that the Melanesian bow-culture may be traced as an essential factor in North American civilizations. In the brief discussion of the several instances given, it is apparent that not only does the writer show too slight an acquaintance with the facts relating to North America, but he violates in every case almost, the principle that the things compared and found similar if they are to prove real relationship, must in themselves possess some distinctive character, and not be simple and widely distributed. Dr. Graebner's theory, moreover, assumes that these elements of Melanesian culture reached America by way of northeastern Asia and Bering Strait, and while this is perhaps not wholly beyond the bounds of possibility geographically, it is contradicted by practically all historical and other evidence and probability. With few exceptions there is no evidence that cultural elements have passed from Asia eastward to America by way of Bering Straits, but on the contrary much evidence has in the last few years been brought forward to show that in fact the reverse has occurred, and that American influences have passed westward into Asia.

For North America, therefore, the case for the Melanesian bow-culture seems extremely weak, and indeed Dr. Graebner himself admits that, as compared with South and Central America, his evidence is scanty. It is necessary thus to examine briefly the argument presented for the presence of this Melanesian culture in the southern continent. At the very outset one is, to say the least, surprised to find in passing that solely from the occurrence of skin cloaks, round huts and coiled basketry, the Fuegians are regarded as repre-

sentatives of the early Australian culture. The willingness here shown to rest conclusions of far-reaching import on foundations of such extremely tenuous nature, can not fail, it seems to me, to lead us to look with some distrust at the author's other conclusions, and to accept them only with great caution.

Turning, however, to the Melanesian bow-culture, the area where this makes itself most strongly felt is said to be the northern and northwestern part of the continent. Here the self-bow of flat cross-section is the prevailing type; here in Guiana, Venezuela and Colombia the pile-dwelling is found; and here pottery (simply as such) is said to reach its highest development. In respect to the latter, a further instance is given of the author's incomplete acquaintance with the field with which he is dealing, in that the distribution given for pottery as "south as far as the Gran Chaco" wholly ignores the well-known fact of its extension to central Chile and far into Patagonia. Simple twilled basketry which is well-nigh universal throughout the northern two thirds of the continent is again brought forward as evidence of Melanesian influence, as is the use of tobacco and the pipe, the hammock and the paddle with cross-handle. Other elements noted are communal houses, head-hunting and skull-cults, and the use of the squatting human figure and the spiral in art. Associated with the Melanesian bow-culture in Melanesia itself is the so-called two-class matriarchal culture, and elements belonging to it, in the form of masked dances, knobbed clubs, plank canoes, pan-pipes and signal-drums are found also in South America. The fact that the chief center for all these elements of Melanesian culture lies in the northern and northwestern part of the continent suggests, says Dr. Graebner, their intrusion from Cen-

tral America and Mexico, where indeed he proceeds to show their presence.

In respect to most of the evidence thus brought forward for South and Central America, the same criticisms may be made as in the case of North America, and in many instances with added force. Here, as there, the mutual relations of the various cultures within the area are largely overlooked, and such well-established facts as that of the northward dispersal and migrations of the Carib and Tupi tribes are completely ignored. The propriety also of assuming that a feature so characteristic and widely distributed in South and Central America as the hammock has been introduced there from Melanesia where its occurrence is, on the contrary, extremely rare, seems rather questionable.

One of the strongest arguments against the validity of the Melanesian bow-culture theory as outlined by Dr. Graebner is, however, furnished curiously by the author himself, in the very abundance of the evidence and the closeness of the similarities which he claims for South America. The essence of the theory is that this Melanesian culture has, as a coordinated and intimately connected group of elements, been transmitted as a unit to the southern continent by way of eastern and north-eastern Asia, Bering Straits and North America. Now as the theory has not the temerity to assert the actual migration of Melanesian peoples from Melanesia through Asia and North America to the southern continent, it follows that the spread of the culture-complex must have been in the nature of a slow transmission from tribe to tribe, each in turn receiving the various elements, and incorporating them into the fundamental structure of its culture, before transmitting them to the next. That any such heterogeneous and not inherently related group of cultural

elements could survive unchanged transmission through scores of different tribes belonging to several distinct races; passing through the whole gamut of varied environments from the tropics to the Arctic circle and back again to the tropics; such transmission lasting necessarily over a period which must be reckoned in centuries or thousands of years; this is an assumption which is not merely beyond reasonable probability but is contradicted by almost all historical and ethnological evidence. It is to deny absolutely the well demonstrated fact that cultural elements when borrowed are subject to far-reaching and often fundamental modifications in accordance with the peculiar psychological characteristics of the borrowers and the environment in which they live; it is to assume that not even in the case of such absolutely elementary and natural things as the use of the skins of animals as protection against the weather, or of a spoon or a communal dwelling, could these have been developed independently and without historical relation; it is, in spite of Dr. Graebner's disclaimer, to throw aside the hard-learned lessons of the past two or three decades derived from the study of mythology, and to revert to the standards of a previous generation, and assume that similarities, whatever their nature and wherever they may be found, can only be explained as due to a common origin.

If then we must, as I believe, regard the theory proposed by Dr. Graebner of the presence of a Melanesian bow-culture in America as in no sense demonstrated, as fundamentally false in method and as exemplifying the most extreme position in the revolt against the theories of independent development, it does not follow that it must be barren of results. Indeed, its value lies, it seems to me, in the fact that it calls serious attention to the existence of

a really remarkable series of parallelisms between certain elements of American and Oceanic cultures, some of the more important of which, however, to my mind, the theory as proposed fails to note. That such parallels existed has for years been known, but hitherto little systematic attempt has been made to gather or explain them. The obvious suggestion has of course been made that they were the result of culture contacts along the Pacific Coast, of Oceanic with American peoples, but beyond this, little has been done. In part this has no doubt been due to the fact that most investigators have felt that our knowledge, particularly in regard to South America and much of Oceania itself, was still too incomplete to make a detailed study of the question profitable. Although I share in this feeling, I may perhaps be permitted in closing to point out a few of the facts which seem to me of special significance, and to urge the need of very thorough investigation of the whole field.

To my mind the most striking and for the purposes of tracing cultural relations, perhaps most important elements in common between the Oceanic area and America are, the true plank canoe, the use of a masticatory with lime, head-hunting and associated skull-cults, the blow-gun, throwing-stick, the hammock and perhaps the institution of the men's-house and certain peculiar masked dances and forms of masks in use in Papuan Melanesia and in America only in parts of Brazil. Of these the first three are either wholly confined to or reach their highest development on the Pacific coasts of both American continents, and the last three (with the exception perhaps of the men's-house) together with the third and fourth are confined to northwestern and northern South America and the immediately adjacent parts of Central America, with, in

the case of the blow-gun, such parts of North America as have been influenced by Carib and Arawak cultures. Compared with the self-bow, the use of coiled pottery, twilled basketry, the spoon, paddle with cross-handle and the communal dwellings of the Melanesian bow-culture, these are for the most part far from being simple affairs, and occur, moreover, with few exceptions, only in America and Oceania together with the adjacent parts of southern Asia. Six at least of the elements (the plank canoe, use of a masticatory with lime, head-hunting and skull-cults, blow-gun, men's-house and peculiar form of mask and masked dances) may be said to be in varying degrees exotic in American culture, in that their distribution is limited and that they are in contrast to the usual and prevailing American types. Four at least (the plank canoe, use of a masticatory with lime, head-hunting and skull-cults and the institution of the men's-house) are on the other hand of very wide and continuous distribution in Melanesia, Indonesia and southeastern Asia. To this list of cultural coincidences may be added among others the curious and ingenious process of polychrome dyeing known in Indonesia as *Ikat*, and which occurs except for the region of Indonesia and adjacent southeastern Asia nowhere else, so far as known, but in Peru.

In any attempt at explanation of these facts, the strong concentration of the elements in America on the Pacific coast and in the western portions of the two continents, and their almost total absence in the eastern parts, seems of considerable importance. In this connection the as yet only fragmentary evidences of early migrations in South America from the Pacific coast eastward into the Orinoco-Amazon area must not be lost sight of. From this distribution, the explanation

which most readily suggests itself is of course the old one of direct contact along the Pacific coast. Elements of material culture might well be adopted thus as a result of the chance drifting ashore of a canoe with a handful of survivors, or even without these, from the region to the west; and the sporadic character of the occurrence of such features as the plank canoe, known only in Chile and on the coast of southern California, might thus naturally be explained. The difficulty, however, in attempting to explain the whole problem in this way lies in the fact that it is not with the migratory and sea-roving Polynesians that the cultural coincidences are strongest, but rather with the Papuan (as opposed to the Melanesian) tribes of New Guinea and with the older cultures of Indonesia. The Papuan tribes are not, so far as we know, a markedly seafaring people, and so far no evidence of their actual presence east of the 180° meridian has come to light. The people of Indonesia also, among whom the resemblances are found, although far more capable navigators, have nevertheless left no certain traces of their presence to the eastward of the Moluccas and the western end of New Guinea. Moreover, the Polynesians could hardly have served as the intermediaries through whom these elements were transmitted, as they themselves show, except for the plank canoe, little trace of them. Unless, then, strong evidence should come to light of an earlier more easterly extension of Papuan and Indonesian peoples, or some explanation be offered for the almost complete absence of the features in question among the Polynesians, the solution of the problem by supposing a direct transmission across the Pacific seems barred by the facts of geographic position and history. A similar result seems also to appear if the attempt is made to trace the elements

by way of the Asiatic and North American littoral. Thus in the present state of our knowledge, neither by way of the long, circuitous route through Asia, Bering Straits and Alaska, nor by the more direct route across the Pacific can we satisfactorily account for the series of striking coincidences in culture between western America and particularly western South America, and Oceania with the neighboring parts of southeastern Asia.

Such a negative conclusion or verdict of "not proven" is generally most unsatisfactory. In the present case, the coincidences are so striking, in both character and distribution, that we are almost forced to believe in some sort of historical connection. But I believe we should for the present continue to be cautious. The possibility of independent development must not be denied even in the case of these quite peculiar features, nor need the fact that only a portion of the American peoples showing coincidences live in similar tropical or semi-tropical environment be regarded as a serious objection to this hypothesis.

To revert again to my title, I believe that in the present state of our information, we must still regard American Indian culture as in all its essentials and in most of its details, as of independent growth, uninfluenced by the cultures of the old world, and recognize that its geographical isolation has in fact proved to be a cultural isolation also, and that although certain curious coincidences undoubtedly exist with parts of Oceania and southeastern Asia, no historical relationship between the cultures of the two widely separated regions can as yet be said to have been established. That with increasing knowledge historical relations may indeed be shown seems to me wholly possible, but its demonstration must rest

upon that fuller knowledge of fact and of the historic sequence of cultures in the respective areas, and on the practise of the general principles of evidence some of which I have here attempted to set forth and illustrate.

Anthropologists are at present, as was recently pointed out by Dr. Rivers in his address as vice-president of the section in the British Association, in the unfortunate condition of not agreeing on fundamental questions of method. We have, it is hoped, left behind us the period of vague and futile theorizing without facts or with too few facts, but there are still many who believe that evolution is the master-key which will unlock all doors, and that by the amassing of more or less heterogeneous and unrelated facts from all over the world a continuous development through definite stages of culture may everywhere be shown. The partizans of independent development based on the theory of the psychological unity of the human mind, are set over against those who believe in the complexity of cultures, and the possibility that by analysis and comparison their historic relationships may be determined, and who would explain similarities in culture between widely separated peoples on this basis or on that of convergent evolution. Here in America we have come to feel, I think, more perhaps than elsewhere, that no one of these theories is a panacea. As a result of the experience of the last decade or so in attempting to outline and define the several culture areas in this continent, we are beginning to realize that these several points of view may all and at the same time be true, and to admit that in a given culture, whereas some elements are undoubtedly the outcome of contact or transmission, others may be the result of evolutionary development, and dependent on the general uni-

formity of reaction to similar stimuli among mankind as a whole; and we are prepared, I trust, to agree that if fact and theory do not conform, it is the latter for which the Procrustean bed should be reserved.

It is in this spirit, then, of insistence on abundant fact and its careful interpretation, without prejudice and unencumbered with rigid theories which will admit of no compromise, that I believe we should approach the question of the independence of American culture; a question which has its greatest interest quite naturally for us in America, but which for anthropology as a whole is also of great and far-reaching importance.

ROLAND B. DIXON

*THE PERCENTAGE OF WOMEN TEACHERS
IN STATE COLLEGES AND
UNIVERSITIES¹*

THE average per cent. of women teachers for all the state colleges and universities is 9+. The average for the schools west of the Mississippi is 13+ per cent., while for the schools east of the Mississippi it is 6+ per cent.

Eleven schools,² which were selected at random, have 149 women teachers. Of these 149, 10+ per cent. are full professors, 5+ per cent. are associate professors, 10+ per cent. are assistant professors and 73+ per cent. instructors.

As to the subjects these 149 women teach, the distribution is: professors, home econom-

¹These figures base upon "Statistics of State Universities and other Institutions of Higher Education Partially Supported by the State," for the year ended June, 1910 (Washington, Government Printing Office), and catalogues of eleven institutions for the year 1910.

²The eleven schools are: University of Arizona, Iowa State College, Miami University, University of Montana, University of New Mexico, North Dakota Agricultural College, Ohio University, University of Oklahoma, University of South Dakota, University of Utah, University of Wyoming.

³ From 1909 report.

ics, 3; English, 2; modern language, 2; history and Spanish, 1; philosophy, 1; political science, 1; school training, 2; fine arts, 1; physical education and elocution, 1, and clinical medicine, 1.

Associate professors: English, 2; chemistry, 2; domestic science, 1; mathematics (and dean), 1; commercial, 1; library science, 1.

Assistant professors: English, 7; domestic economy, 3; Latin and Greek, 2; philosophy, 1; mathematics, 1; public speaking, 1; history, 1.

Instructors: music, 20; modern language, 14; English, 13; natural science, 8; school training, 7; history, 8; physical education, 6;

art, 6; commercial branches, 5; mathematics, 4; domestic science, 5; public speaking, 3; ancient languages, 2; mechanical drawing, 2; kindergarten, 2; Latin and English, 2; elocution and physical culture, 1; pediatrics, 1.

The groups for which women qualify are therefore, in order of frequency: English, music, modern language, domestic science and home economics. In natural science and mathematics they do not often rise above the rank of instructor.

The high per cent. of women teachers west of the Mississippi may be explained by saying that the west is less conservative than the east; that there are more coeducational institutions in the west; that the western schools were founded after women began to compete for college positions, while the majority of eastern schools were founded before this time. Lack of ample funds may also at times have dictated the choice of cheaper service.

The number and per cent. of women in the various schools is given on page 56.

C. H. HANDSCHIN

SCIENTIFIC NOTES AND NEWS

MR. ARTHUR D. LITTLE, of Boston, was elected president of the American Chemical Society at the Washington meeting.

PROFESSOR E. G. CONKLIN, of Princeton University, has been elected president of the American Society of Naturalists.

PROFESSOR ROSS G. HARRISON, of Yale University, was elected for the coming two years president of the American Association of Anatomists at the recent Princeton meeting.

DR. S. J. MELTZER, of the Rockefeller Institute for Medical Research, has been reelected president of the American Physiological Society.

THE Academy of Natural Sciences of Philadelphia has awarded the Hayden Medal in gold for distinguished work in geology to Professor John C. Branner, of Leland Stanford Jr. University.

PRESIDENT TAFT has nominated Dr. Rupert Blue, of South Carolina, as surgeon general of the public health and marine hospital service,

succeeding the late Dr. Walter Wyman. President Taft gave notice that hereafter the term of service of the surgeon general of the public health service shall be limited to four years.

M. HENRI BERGSON, professor of philosophy at the Collège de France, has been appointed visiting French professor of Columbia University for the year 1913. M. Bergson has also been appointed Gifford lecturer at Edinburgh.

THE organ of the Japan Peace Society gives an account of the visit of Dr. David Starr Jordan, president of Stanford University, in August, September and October, of last year, undertaken under the auspices of the Japan and American Peace Societies. Dr. Jordan gave a large number of addresses, mainly on peace and arbitration, at Tokyo, Yokohama, Sendai, Nagoya, Okayama and Osaka. At Tokyo between September 13 and 18, Dr. Jordan gave as many as ten addresses, not including after-dinner speeches.

DR. W. A. CANNON, of the Desert Laboratory, is acting director of the Department of Botanical Research of the Carnegie Institution during the absence of Dr. D. T. MacDougal, who is traveling and studying desert conditions in Upper Egypt and portions of the Soudan.

MR. MYRON L. FULLER, for many years a geologist on the United States Geological Survey and chief of the Eastern Section of the Division of Hydrology from 1903-07, has formed an association with Mr. Frederick G. Clapp, also formerly of the Geological Survey, to act as consulting experts in all branches of geological engineering, especially in water supplies, bridge and dam foundations, ore deposits, oil and gas.

THE *Strand Magazine* has obtained a vote to determine the ten greatest men now living. The speaker of the house of commons drew up a list of eighteen men and other distinguished men voted for names by reduction and substitution. The final list in the order of the number of votes was: Edison, Kipling, Roosevelt, Marconi, Lister, Chamberlain, Roberts, William II., Metchnikoff.

DR. A. D. IMMS, professor of biology, University of Allahabad, has been appointed forest zoologist to the government of India.

A REUTER's telegram states that Dr. Kinghorn, who is at present in Northwestern Rhodesia, has transmitted the *Trypanosoma rhodesiense* by means of *Glossina morsitans*.

At a meeting of the Pellagra Investigation Committee on December 12, in London, Dr. Louis Sambon and Dr. A. J. Chalmers gave an account of the work of the Field Commission on Pellagra, from which they have just returned. The commission visited Hungary, Roumania, the Austrian Tyrol, North Italy and Spain, examining the districts in the several countries where pellagra prevails.

DR. WILLIS RODNEY WHITNEY, director of the research laboratory of the General Electric Company, lectured before the Middletown Scientific Association on January 9, his subject being "Research Laboratory Notes."

PROFESSOR G. F. SWAIN, of Harvard University, has returned to Cambridge from a trip to the middle west, where he gave the annual Sigma Xi lectures at the University of Kansas, the University of Missouri and Washington University.

At the recent meeting of the American Physiological Society in Baltimore Dr. W. B. Cannon, of the Harvard Medical School, delivered a memorial address on the late Professor Henry Pickering Bowditch.

MAJOR CLARENCE EDWARD DUTTON, U.S.A., retired, distinguished for his services in the civil war and later in the ordnance corps of the army and eminent for his contributions on volcanoes and earthquakes, died on January 4 at his home in Englewood, N. J., aged seventy years.

DR. ARTHUR V. MEIGS, of the third generation of a family of noted physicians and surgeons, and widely known as a physician and author of medical works, died on December 31 at his home in Philadelphia, at the age of sixty-one years.

MR. GEORGE R. M. MURRAY, F.R.S., for many years on the staff of the department of

botany of the British Museum, known for his contributions on fungæ and algæ, died on December 15, aged fifty-three years.

M. PAUL TOPINARD, the distinguished French anthropologist, has died at the age of eighty-one years.

M. RADAU, member of the astronomical section of the Paris Academy of Sciences, has died at the age of seventy-seven years.

PROFESSOR ODILON MARC LANNELONGUE, the celebrated pathologist and surgeon, died in Paris on December 22, at the age of sixty-one years. At the time of his death he was president of the Paris Academy of Medicine and a member of the French parliament.

THE third annual meeting of the Paleontological Society was held at the new National Museum building, December 28-30, 1911, with 59 of its 136 members present. The results of the election of officers for the society for 1912 were as follows:

President—David White, Washington, D. C.

First Vice-president—J. C. Merriam, Berkeley, Cal.

Second Vice-president—Rudolf Ruedemann, Albany, N. Y.

Third Vice-president—E. W. Berry, Baltimore, Md.

Secretary—R. S. Bassler, Washington, D. C.

Treasurer—Richard S. Lull, New Haven, Conn.

Editor—Charles R. Eastman, Cambridge, Mass.

THE American Society for Pharmacology and Experimental Therapeutics held its third annual meeting in the Pharmacological Laboratory of the Johns Hopkins University, December 27 and 28. Thirty-one papers and demonstrations were presented and discussed. On the afternoon of the 27th there was a joint meeting with the American Physiological Society. Dr. J. J. Abel was reelected president and Dr. John Auer was elected secretary. The following new members were elected: T. S. Githens, of the Rockefeller Institute; Y. Henderson, of the Yale Medical School; D. R. Hooker, of the Johns Hopkins Medical School; L. Nelson, of the Harvard Medical School; J. D. Pilcher, of the Western Reserve University Medical School, and G. B. Roth, of the University of Michigan.

THE seventeenth meeting of the Association of Teachers of Mathematics for the Middle States and Maryland was held at Columbia University on Saturday morning and afternoon, December 2. The morning program consisted of the following papers: (1) "An Allegation applied to the Calculations of Analytical and Industrial Chemistry," by W. A. Ballou, Pratt Institute; (2) "What Subjects in the High School Mathematics are of Greatest Use in Preparation for Analytical Geometry and Calculus in College," by W. J. Babb, of the University of Pennsylvania, and A. S. Gale, of the University of Rochester. In the afternoon the program consisted of (1) "Educational Values in Mathematical Instruction," by H. E. Hanks, of Columbia University; (2) "Provisional Report of the National Geometry Committee of Fifteen," by Howard F. Hart, of the Montclair High School. The following officers were elected:

President—I. J. Schwatt, University of Pennsylvania.

Vice-president—A. E. King, Erasmus Hall High School, Brooklyn.

Secretary—H. F. Hart, Montclair High School, Montclair, N. J.

Treasurer—Susan C. Lodge, Philadelphia College Institute, Philadelphia.

Council Members—A. S. Gale, University of Rochester, Rochester; J. T. Rowe, Wm. Penn High School, Philadelphia; Harry English, Division of High School Mathematics, Washington.

THE first annual dinner of the Edinburgh University Club of North America, was held on December 27, at the University Club in the City of New York. Professor Clarence Webster, Chicago, the president of the club, occupied the chair, and about sixty alumni of Edinburgh University were present. Congratulations upon the birth of the club were received from the chancellor of the university, the Right Hon. Arthur J. Balfour, M.P., from Principal Sir William Turner, K.C.B., from the last lord rector, Lord Haldane, of Cluan, from the university parliamentary representative Sir Robert Baunatyne Finlay, from Sir Alexander R. Simpson, Dr. George A. Gibson and others. The Hon. Joseph H. Choate, LL.D., Edin., discoursed eloquently

upon "Our Alma Mater"; the Right Rev. Frederick Bishop Courtney, upon "Scottish Character"; Professor Prince, Ottawa, Canadian Commissioner of Fisheries, upon "United States" and Sir James Grant, Ottawa, upon "Canada." The club bard, Mr. Robert Easton, charmed every one with his rendering of Scotch songs. Great enthusiasm prevailed. The first function of the club was a marked success. Graduates and undergraduates of the university are eligible for full membership of the club. Fellows and licentiates of the Royal Colleges and post-graduate students of Edinburgh University may, as associate members, attend the annual dinners. Any who are interested are invited to communicate with the secretary, Edinburgh University Club, 20 East Sixty-ninth St., New York City.

We learn from the *British Medical Journal* that on December 6 a dinner was given to welcome Professor Newstead on his return from the sleeping sickness expedition to Nyasaland and to wish godspeed to Dr. Harald Seidelin on his departure on a yellow fever expedition to Yucatan. Owing to having contracted a chill, Professor Newstead was unable to be present. Sir William H. Lever, who was in the chair, in proposing the toasts of the evening, remarked that the trustees of Sir Alfred Jones had intimated that they would come to the assistance of the school, and, in addition to better accommodation in Liverpool, it was proposed to establish a laboratory on the West Coast of Africa, where investigations into tropical diseases might be made on the spot. The government had given support to their movement, but he considered it was not adequate, and he echoed Sir Owen Phillips's opinion that it should grant to the London and Liverpool Schools £10,000 annually. If America had succeeded in making the Panama zone healthy, there was no reason why they should not, with adequate financial support, make West Africa sanitary.

A MEETING of the trustees of the Beit Memorial Fellowships for Medical Research was held on Tuesday, December 19, when ten fellows were elected. Each fellowship is of the

annual value of £250. The usual tenure is for three years, but the trustees have power in exceptional cases to grant an extension for one year.

UNIVERSITY AND EDUCATIONAL NEWS

MR. JACOB H. SCHIFF has given \$100,000 to Cornell University to promote studies in German culture.

THE million dollar fund for the further endowment of the Medical School of Western Reserve University has been completed.

DE PAUW UNIVERSITY has just brought to a successful close the campaign to raise \$400,000 to meet the conditional gift of \$100,000 from the Rockefeller Educational Board. The subscriptions total a little more than \$440,000. This will make the productive endowment of the university something above \$1,000,000.

ON December 13 an anonymous gift of £30,000 was made to the University of London, to be devoted to the erection at University College of the buildings for the new school of architecture, resulting from the amalgamation of the architectural department of University College and King's College. Any balance is to be used for providing studios for the teaching of sculpture and the rearrangement of the school of fine art and for the department of applied statistics, including the laboratory of eugenics.

THE Supreme Court of Illinois, on the final day of its fall term, failed to hand down a decision in the case involving the validity of the appropriation made by the legislature for the Medical School of the University of Illinois.

FOLLOWING the custom of recent years, the United States government has sent officers of the army and navy to the Massachusetts Institute of Technology to receive instruction in electrical engineering. These are in addition to the graduates of the Naval Academy who are sent to take a course in naval architecture. This year the Naval Academy is represented by Ensign G. K. Calhoun, who was graduated from Annapolis in 1908. He has recently been stationed at the United States Naval

Observatory at Washington where he has done considerable original work in wireless telegraphy, ship propulsion, gyroscopic compasses and chronometers. The army is represented by Captain Edward Canfield, West Point, 1901, and First Lieutenant F. Q. C. Gardner, West Point, 1904. Both officers have been connected with the Coast Artillery Corps, Captain Canfield being stationed at Puget Sound and Lieutenant Gardner at Fortress Monroe. Both men will pursue a special course in electrical engineering.

THE council of the University of Paris has sanctioned a scheme for an exchange of students between the universities of Paris and London.

THE Veterinary School of Lyons, France, said to be the oldest in the world, will celebrate the hundred and fiftieth anniversary of its foundation next May.

DR. CLYDE A. DUNIWAY, of the University of Montana, has been informed by the Board of Control that he will not be reappointed as president of the university. It is understood that this action has been taken because President Duniway refused to appoint a local politician as dean of the law school of the university.

DISCUSSION AND CORRESPONDENCE

WHAT IS BIOLOGY AND WHAT IS A "BIOLOGICAL SURVEY"?

THE occasion for the present note is found in the recent publication of "A Biological Survey of Colorado."¹ Probably most students of plants and animals have long wished that the word "biology" had never been coined. It is so often misunderstood by the non-scientific person. In the days of the old taxonomy and of the former rigid morphology there were few people really interested in both plants and animals. With the advent of ecology, and more recently of genetics, botanists and zoologists have been brought together and

¹ Issued as "North American Fauna," No. 33, as a publication of the Bureau of Biological Survey, Washington, 1911. The author, Merritt Carey, is stated to be "Assistant Biologist, Biological Survey."

it has seemed that perhaps there might be, after all, such a subject as "biology."

But now when it seemed that the word "biology" might really have a meaning there is issued from Washington this report, which even at very first glance belies its title. The real nature of the publication is indicated in the "Letter of Transmittal" in which it is stated that

The report consists of three parts. The first characterizes the five life zones which traverse the state, defines their extent and limits and discusses their agricultural possibilities. The second consists of a complete list of the mammals of Colorado with brief notes on their habits, distribution and economic relations. The third is a list of the principal trees and shrubs of the state observed by the assistants of the biological survey during the progress of work in the state, with annotations as to their distribution and abundance.

Just why such an ambitious title as "A Biological Survey of Colorado" should be used for this report is nowhere stated and certainly is not apparent from internal evidence.

If this were the first study of the kind ever made in Colorado it would be a most excellent work. The material here presented, however new to the author, is very little of it new to science. Warren's "Mammals of Colorado," published in 1910, covers the mammals quite fully and numerous publications on ornithology and botany go far beyond the present report in most of the things mentioned in those branches. There are references to various publications on mammals and to one single botanical report, but apparently all the other information given by the author is from his own work. It is little short of marvelous that a young man with so little knowledge of the state, of its climate, its flora and its fauna has been able to prepare so good a report.

The discussion of life zones is conspicuous for that perfect independence of thought characteristic of those who know nothing of the writings and opinions of others. It would seem worth while, before writing about the native animals or plants of a state, to consult the published works of men of science resident in the state. Thus many laughable mistakes might be avoided.

It is a question worth considering whether the writer of "a biological survey" of any state would not do well to visit the museums within the state and make himself known to the naturalists who might help him in his work. The writer of "A Biological Survey of Colorado" according to his own account made his start from Boulder, but apparently did not take the trouble to visit the university there nor the museums in Denver, only 30 miles away.

From a reading of the report under consideration one would imagine that his was the first biological work ever undertaken in the state, save certain previous work on mammals, to which scant reference is made. Even if "a biological survey" means an account of one's own personal experiences in collecting mammals it would seem the part of candor to let the reader know that other men of science have at least looked upon the plants and animals of the region visited.

It is to be hoped that the next time the Bureau of Biological Survey at Washington authorizes the prosecution of "a biological survey" of any state, provision will be made to make the body of the report agree with the title. It would be interesting to know of naturalists generally whether they conceive "biology" to be synonymous with "mammalogy" and also to know whether an account of field trips made by one man is really "a biological survey" of a state.

PHYSICAL LABORATORY INSTRUCTION

THE article in the December 15 number of SCIENCE, p. 823, by G. W. Stewart on "An Opportunity for the Spirit of Research in Laboratory Instruction in Physics," seems to be a move in the right direction. One aid towards securing this spirit of research is to be found in dispensing with detailed instruction sheets, and with apparatus that is set up and in adjustment. The best way in which to give instructions is in the form of a lecture,

in which the underlying principles are explained, and the object of the experiment is clearly pointed out. In this way a student is permitted to approach the experiment in the same way in which the first person who did it approached it, *i. e.*, as a research problem.

The lecture system necessarily involves the use of some kind of grouping of the experiments. This last, however, is an advantage, as it permits running the laboratory and classroom work parallel to one another.

Another aid with the same object as above, is not to insist too strongly on precise measurements by elementary students. The elementary student is often frightened by the task of measuring a thing down to one one-hundredth of one per cent. with a strange piece of apparatus. Only after the student has acquired confidence in himself as an experimenter should great accuracy be insisted upon. However, from the very first the student should express the percentage of error of his observations. By accepting all work at first, with a percentage of error simply indicating poor experimental ability, the student is encouraged to try the experiment. This last also does away with the incentive to "doctor the results." On the other hand, the student dislikes to pass in an experiment with a larger percentage of error than that obtained by the best experimenter in the class, so that he tries his hardest to get a correct result.

The foregoing are simply aids to the spirit of research, the principal thing being the "attitude of the instructor" rather than any particular method.

CHESTER A. BUTMAN

PHYSICAL LABORATORY,

THE MEETINGS OF AFFILIATED SOCIETIES

TO THE EDITOR OF SCIENCE: I feel like seconding all that Professor Morse has said in a recent (December 22, 1911) number of SCIENCE in regard to the custom that has arisen among some of the "affiliated societies," especially the zoologists, of holding the winter-meeting at a different place from that in which the American Association meets.

As I stated before the zoologists at the recent meeting at Princeton, there was a very strong feeling expressed by a number of prominent zoologists at the Washington meeting against the present method of meeting at different places, especially when the meetings are at the same time.

I should like to see a general expression of opinion, through these columns, or otherwise, upon this subject, especially by those zoologists who are members of the American Society of Zoologists. Such an expression of opinion might serve, in some measure, as a guide to the committee that was appointed by the Society of Zoologists to look into the matter.

ALBERT M. REESE

QUOTATIONS

THE BRITISH INSURANCE ACT

"BUYING men's all right—the trouble is they won't stay bought." Such was the reflection of a disillusioned political boss. In the same way it is often easy enough to "do" men. The trouble is they won't stay "done." Mr. Lloyd George is finding that out in the case of the doctors. The members of the medical profession are notoriously bad men of business. They are very busy, and they find it impossible, unlike most other professionals, to divide their lives into water-tight compartments of work and leisure. They are harassed at all hours by calls upon their time and, still more, upon their mental energy. Hence they can attend very little to their professional interests. This fact made them and their leaders an easy prey to so astute and persistent a diplomatist as Mr. Lloyd George. Early in the game he saw that from the point of view of public agitation and public opposition to his measure, it was far more important to conciliate the friendly societies and prevent their rising in revolt than to make concessions to the doctors. Accordingly he "put his money on the societies," and merely put a little chloroform on a handkerchief in the case of the doctors, whispering to them at the same time that it would be all right when they woke up. The suggestion was that they would be

able to make any terms they liked with the local insurance committees when once these were formed. This simple but most successful artifice, and the curious belief entertained by the doctors up to the last moment that Mr. Lloyd George would never dare to pass his bill without having come to a clearer understanding with them that they would work his scheme, prevented the medical profession doing what they might have done, and ought to have done—that is, organize pressure upon members of Parliament and upon the House of Lords in order to prevent the bill passing till their claims had been properly recognized. Now, however, that the bill has actually passed, and the task of putting things right is multiplied a thousandfold in difficulty, the doctors are beginning to wake up and see the terrible position into which they have got themselves, or rather, as the rank and file would say, into which their leaders, inexperienced in political negotiation, have got them. They are at last beginning to understand the very simple rule of strategy—"if you allow yourself to be taken in detail, you are lost." Instead of the doctors being able to make good terms with the individual insurance committees, they are beginning to see that the only chance of their not being bullied into starvation rates by those committees is for the whole profession to hold resolutely together and not to allow themselves to be pounded up piecemeal. At the great meeting at the Queen's Hall on Tuesday night it was obvious that the medical profession is at last seriously alarmed. They realize that they have been "done," but they do not intend to stay "done." Unless we very much mistake the signs of the times, the medical profession mean to organize resistance to the act and to refuse to make any agreements under it, unless and until their just claims are recognized. And here we may interpose that if Mr. Lloyd George offers to negotiate with them, as we fully expect he will, they will, if they are wise, not be content for a second time with promises and general assurances. They must insist that whatever concessions are made shall be embodied in an amending act, to be passed as

soon as may be after Parliament reassembles, or, at any rate, before the date at which the measure comes into operation—i. e., July 1 next. They will be told, of course, that such a suggestion is absurd and that nothing can be done till Home Rule is out of the way. "If nothing else forbade it, Mr. Redmond would not," etc. The only answer to this is, "If you can not find time, you can not have our assistance in working your measure."

An even more important sign that the doctors are growing alive to the position of deadly peril in which their interests are placed under the act is to be found in the quasi-referendum which has been organized by a medical newspaper, *The Practitioner*. The journal in question sent out a voting paper to the 29,567 medical practitioners of Great Britain, asking them the following question:

Are you satisfied that the arrangements made for the profession with regard to the medical service now embodied in the National Insurance Bill would justify you in giving honest and adequate service to the insured?

The result of the poll was most remarkable. 20,712 replies have already been received, with the result that 20,149 doctors have answered "No"—that is, have declared that they are not satisfied that the arrangements of the Insurance act will justify them in giving adequate service to the insured. Only 352 out of the whole 29,000 have expressed themselves as satisfied, while 211 have asked questions—a fact which would seem to indicate that they are not satisfied. Very naturally *The Practitioner* realizes that it is no use to stop at eliciting the dissatisfaction of the profession. Accordingly it has now asked the doctors of Great Britain—Ireland is not affected—or, rather, those who are dissatisfied with the act, to give the following pledge:

Feeling that the present National Insurance Act is unjust to the medical profession, I hereby pledge my word not to accept any service whatsoever under it. I stipulate, however, that unless at least 23,000 members of my profession in Great Britain combine with me in this pledge, I am to be freed from it.

The pledge is very fairly as well as very ingeniously worded. A doctor whose livelihood depends upon his practise might well shrink from entering upon an obligation which he might find left him isolated. To say, however, that he is willing to run the risks of refusing work under the act if others will stand by him is a very different matter. And here we may remark that the number, 23,000, is not taken at haphazard. It is calculated that at the very least 8,000 doctors will be required to work the insurance scheme. Therefore if 23,000 of the medical men of the country agree to stand together in not working it, the act can not possibly be put into successful operation. The result of *The Practitioner's* second move will, we take it, not be announced before these pages have gone to press, but we shall be very much surprised if the second voting does not correspond with the first. If it does, and some 23,000 doctors are pledged not to take service under the act, the doctors will have done what, in our opinion, the Lords ought to have done: they will have secured a period of delay in which just and reasonable terms can be made with the profession as a whole, and any attempt to take the doctors in detail defeated.

Before we leave the subject we must point out one or two misapprehensions which have arisen, or are likely to arise, in the public mind in regard to the movement. In the first place the public must not suppose that the doctors are threatening to withhold medical advice from the poor or from the sick, the injured or the dying, until they have got their terms. Nothing in the nature of a refusal of their services is threatened or is contemplated by the doctors. They merely say that they will not enter into the special and peculiar contracts which they will be required to make under the act if they are to obtain its so-called benefits. The result will only be that medical attendance on the poor will go on exactly as it is going on at this moment. The poor and the artisans will be looked after by the doctors in the future just as they have been looked after by the doctors in the past and are being looked after now. There is not the slightest ground for the suggestion that the doctors are trying to ex-

tort terms by a strike or are doing anything which would disgrace the most humane and the most self-sacrificing of all the professions. As before, they will do what no other profession does: give an immense amount of gratuitous service, not because they like doing work without being paid any more than other men, but because it is their honorable tradition to relieve suffering first and consider the question of payment afterwards—to let the sick and the injured have medical aid gratis or for some derisory remuneration rather than that men and women should suffer when that suffering can be relieved. That noble attitude can, and will, be maintained perfectly well even if the doctors refrain from signing the unfair contracts which will be presented for their signature under the act. The doctors are not proposing to strike or to put an end to any existing contract, but merely to refuse to make new ones which they consider unfair. In truth, the language that has been used about the strike of the doctors, even by the doctors themselves, is chiefly misleading rhetoric. There is no analogy whatever between the action of the medical profession and that of strikers in the great majority of cases. The doctors are not demanding higher fees and better conditions of work than they get at present, but are merely refusing to accept what they are confident will turn out to be lower fees and worse conditions of work.—*The Spectator*.

SCIENTIFIC BOOKS

The Changing Chinese, Oriental and Western Cultures in China. By EDWARD ALSWORTH ROSS, Ph.D., LL.D., Professor of Sociology in the University of Wisconsin. New York, The Century Co. 1911. 8°. Pp. xvi + 356. Price \$2.40, postage 18 cents.

Almost on the day that the great Chinese insurrection broke out, this book emerged from the press. The coincidence is at least fortunate from whatever point of view one sees it. The book is not exactly a prophecy, and it is still too early to speak of the fulfillment of any one's prophecy. But the reader of the book will be put in possession of facts

and information that will greatly aid him in his efforts to account for the events of to-day.

It is well known that Dr. Ross spent many months in 1910 traveling through China. He went for the express purpose of studying the sociology of China, and although the numerous authors of recent books on the celestial empire have usually had a much longer experience in that country than Dr. Ross, still they have not for the most part gone there for a specific purpose, and their accounts are more or less incidental to other objects that called them there. None of them, so far as I am aware, are professional sociologists, and their observations are chiefly centered on political affairs. Of course they treat social matters too, but only from the ordinary standpoint, and not in a systematic and scientific way. Dr. Ross's equipment for observing social phenomena enabled him to see more in a few months than some would see in many years. It also enabled him to interpret facts in the light of a great store of scientific knowledge of human society in general. Whatever he observed he instantly saw the full meaning of, and was thus able to correlate oriental with occidental conditions. The entire history of the western world was at his command, and by this means he could locate China in its proper part of the historic panorama. Instead of considering the Chinese such a strange people as most observers do, because they are unlike ourselves, he simply ran his eye back along the path of European history till he found the epoch at which Europeans were what the Chinese are now. He found it in the middle ages, and he says:

Not that there is anything queer in the working of the Oriental brain. Not in the least. Their popular thought is unripe, that is all. The bulk of the Chinese match up well with our forefathers between the fourteenth and seventeenth centuries. For in the Middle Ages white men were just as haphazard, casual and uncritical as are the yellow men to-day. They looked for "signs and wonders in the heavens" and trembled at comets. They held that blood-root, on account of its red juice, must be a blood purifier; liverwort, having a liver-

shaped leaf, will cure liver disease; eyebright, being marked with a spot like an eye, is good for eye troubles; and so on. They fasted, exorcized demons, burned witches, trusted talismans, paraded sacred images, wore relics of the saints, sought the king's touch to cure scrofula, marched in religious processions to bring change of weather and hung consecrated bells in steeples to ward off lightning. It was the rise of the natural sciences that cleared the fog from the European brain. In the building of astronomy, physics, chemistry and physiology were wrought out certain methods—observation, measurement, trial and error, experiment—which were as helpful for practical life as for science. For a method that connects cause and effect may also light up the relation between effort and result (pp. 315-316).

In some things the Chinese would seem to belong to a still earlier stage in the development of Caucasian peoples, for the absence of chimneys and glass windows carries us back to the first century of our era. They were unknown to antiquity, but were found in the ruins of Pompeii, which was buried in the year 79 A.D. In their apparent ignorance of the value of milk as food the Chinese go all the way back to the Homeric period.

One of the most important points brought out by Dr. Ross, known of course to others, but little emphasized, is the astonishing confirmation that China furnishes of the great "principle of population" of Malthus. Nearly all the woes that China suffers are due directly or indirectly to the operation of this principle, and we may say, secondarily, to its ignorance of it. We thus read:

For a grinding mass poverty that can not be matched in the Occident there remains but one general cause, namely, *the crowding of population upon the means of subsistence*. Why this people should so behave more than other peoples, why this gifted race should so recklessly multiply as to condemn itself to a sordid struggle for a bare existence can be understood only when one understands the constitution of the Chinese family (p. 96). . . . For adults over-population not only spells privation and drudgery, but it means a life averaging about fifteen years shorter than ours. Small wonder, indeed, for in some places human beings are so thick the earth is literally foul from them. Unwittingly they poison the ground,

they poison the water, they poison the air, they poison the growing crops (p. 104). . . . Here are a people with standards, unquestionably civilized—peaceable, industrious, filial, polite, faithful to their contracts, heedful of the rights of others. Yet their lives are dreary and squalid, for most of their margins have been swept into the hopper for the production of population. Two coarse blue cotton garments clothe them. In summer the children go naked and the men strip to the waist. Thatched mud hut, no chimney, smoke-blackened walls, unglazed windows, rude unpainted stools, a grimy table, a dirt floor where the pig and the fowls dispute for scraps, for bed a mud *kang* with a frazzled mat on it. No woods, grass, nor flowers; no wood floors, carpets, curtains, wallpaper, table-cloths nor ornaments; no books, pictures, newspapers nor musical instruments; no sports nor amusements, few festivals or social gatherings. But everywhere children, naked, sprawling, squirming, crawling, tumbling in the dust—the one possession of which the poorest family has an abundance, and to which other possessions and interests are fanatically sacrificed (pp. 104-105). . . . Utility reigns supreme; and all it comes to is to feed a dirty, sordid, opium-sodden people living in hovels, wearing coarse, faded blue garments, crippling their women by foot-binding, and letting their boys and girls run about filthy and naked! No music, art, books, poetry, worship, refined association, allure of children, charm of women or glory of young manhood in its strength. No discussions, no politics, no heed to events in the great world. Life on a low plane, the prey of petty cares and mean anxieties. Infinite diligence, great cleverness and ingenuity, abundance of foresight and thrift, few destructive passions; still, a life that is dreary and depressing to look upon (p. 287).

Such is the picture. It is this enormous pressure of population that has so reduced the standard of living, and that makes the Chinese people a drove of pigs, rather than a collection of human beings. It is true that they give reasons for it, and that it forms part of their time-honored customs, so that perhaps it may rather be ascribed to error than to ignorance. The result is the same.

The next most striking fact that looms up is the complete improvidence of the Chinese. By this I mean their failure to look forward to the future or to consider the effect of their

social system upon coming generations. It may be called social, as distinguished from individual improvidence. Of the latter, as Dr. Ross shows, they are not guilty. But they seem to have no social consciousness whatever. That has been true of other peoples at their stage of culture, but on account of the density of population in China the results have been more disastrous there than elsewhere. The great "Indo-Germanic" migration of which we hear so much, by which central and western Asia were depopulated, was doubtless largely due to the exhaustion of the natural resources by man's reckless individualism, but evidence is accumulating of the gradual drying up of these regions as a planetary process, which may be general all over the world. This, however, appears to have been inappreciable in eastern Asia, and there is still abundant rainfall. The entire Chinese empire is highly favored by nature in this respect, and the destruction that has taken place is exclusively the work of man. It is customary with us to condemn the feudal system and to deplore the reservation of vast tracts of country by a landed gentry, but the condition of China leads us to question whether Europe, but for this, might not have also been denuded and made uninhabitable for civilized man. On this point Dr. Ross aptly remarks:

If the Chinese had not so early rid themselves of feudalism the country might have profited, as did Europe during the Middle Ages, by the harsh forest laws and the vast wooded preserves of a hunting nobility; or a policy of national conservation would have availed if begun five centuries ago. Now, however, nothing will meet the dire need of China but a long scientific, recuperative treatment far more extensive and thoroughgoing than even the most enlightened European governments have attempted. Since that is clearly beyond the foresight and administrative capacity of this generation of Chinese, the slow physical deterioration of the country may be expected to continue during our time (pp. 24, 27).

Dr. Ross gives a brilliant description of the ruined condition of the country, especially on pages 22-24, too extended to be reproduced here, but which should be read by all who are interested in the conservation movement in

the United States. It shows what we would come to if nothing was done. It is also a lesson to the *laissez faire* economists and is a fair sample of the legitimate consequences of the *laissez faire* policy in general.

Another modern economic doctrine is here exemplified, namely, that of historical materialism, as it is called, otherwise named economic materialism, economic determinism, or the economic interpretation of history. I do not refer to the facts, which of course can be relied upon, and we have them here on a grand scale, but to the contention that economic effects are exclusively the result of impersonal, or, as it were, of physical laws, with which men as men, and human ideas have nothing to do. That the entire series of degrading conditions in China is due to the ideas and fixed beliefs of the Chinese is clear almost at a glance. We have seen that their terrible overpopulation is the result of an inveterate conviction of the duty of unlimited propagation, which nothing seems able to shake. The same is true of most of their other calamities, which a sound philosophy might have averted. On this point Dr. Ross says:

Chinese conservatism, unlike the conservatism of the lower races, is not merely an emotional attitude. It is not inspired chiefly by dread of the unknown, horror of the new, or fanatical attachment to a system of ideas which gives them confidence in the established. It is the logical outcome of precedent. Change the ideas of the Chinese and their policy will change. Let their minds be possessed by a philosophy that makes them doubt the past and have confidence in the future, and they will prove to be as consistently progressive as are the Germans of to-day (pp. 53-54).

It is perfectly clear that the Japanese awakening has been due to a change in their ideas, and when the Chinese similarly change theirs they too will awake and start in a new direction. That the Chinese are not an "inferior" race, that their intellectual capacity is fully equal to that of the Caucasian, nay, of the Aryan race, is clearly brought out in this book, and no one can foresee the results of a development there, should it ever take place, analogous to the intellectual development of Europe since the middle ages.

There are many great subjects treated in this work which space will not permit us more than to mention. One is the condition of women and the prospect of their emancipation. In China, as in India, the androcentric world view is supreme, and its overthrow seems almost hopeless, but progress is being made even here, and foot-binding at least seems destined to disappear. In the relations of the sexes China is certainly medieval if not positively ancient or even barbaric. There is absolutely no mutuality in the choice of partners. None of the three forms of sexual selection to which I gave special names in 1903, viz., gynexlexis, andrexlexis and amplexlexis (terms which are defined in the Supplement to the Century Dictionary), can be said to exist in China, but a fourth form, which I did not name, but which may be called *altrexlexis*, is universal. This is the selection of wives by third parties—parents, relatives and usually by the house or clan to which the parties belong—and in which neither of the parties to the marriage, least of all the woman, has any voice whatever. Under such a system, which is of course not confined to China, but has widely prevailed in other countries, there can obviously be no romance, and life becomes utterly prosy and uninteresting. But it also shows, as do unnumbered other facts, that there is no psychologic basis in China for a romantic life, that the sentiment underlying it, commonly called romantic love, does not exist in the Chinese constitution, being wanting there as it is in all other races outside of the Caucasian peoples subsequent to the middle ages of European history.

The opium curse of China is treated in an interesting chapter, and the remarkable fact developed is that the crusade against it has been mainly waged by the Chinese themselves. The Christian missionaries residing there, belonging, as they do, to races in which the evil does not exist, have, it is true, cooperated in the movement, but the claim so often made, that they are the chief cause of the progress attained, is utterly unfounded. On the contrary, the strongest resistance that the Chinese

authorities have encountered comes from the British traders, who have taken advantage of the Chinese laws prohibiting the raising of the poppy in China to increase the importation of opium from India. So much for the boasted morality of European nations.

Dr. Ross says nothing of another great moral crusade that the Chinese nation has been long waging, viz., that for the abolition of slavery. For a very full account of that movement we are indebted to Mr. E. T. Williams, who was long Chinese Secretary of the U. S. Legation at Pekin, and was made Consul General at Tientsin in the spring of 1908. Mr. Williams is also a sociologist of no mean order, and is conversant with the entire literature of the science. He treated this subject in the *American Journal of International Law* for October, 1910 (Vol. IV., pp. 794-805; Supplement, Official Documents, pp. 359-373), in an exhaustive article entitled: "Abolition of Slavery in the Chinese Empire." The Supplement contains Mr. Williams's translation of the report of the commission recommending the abolition of slavery and the imperial rescript approving it. The whole is reprinted in pamphlet form.

In all matters relating to the influence of Christianity and Christian missionary work in China our author is decidedly partisan. As an American traveling in China, he was of course largely beholden to American and English missionaries for facilities in getting about, and must have seen a wholly disproportionate part of their influence in the country, and it would have ill become him to speak disparagingly of such things, whatever his real views might have been. But his extravagant praise of them, even where it was deserved, should have been tempered by countervailing considerations which everybody knows to exist. His idea of the ultimate conversion of the Chinese to Christianity is probably Utopian. The hint on page 235 that Christianity might ultimately become the "official religion" of the Chinese empire would be alarming if it rested on any basis of fact. The present humble attitude of the few Christian missionaries in China is no criterion. As

Helvetius said: "Christians are lambs when weak, tigers when strong." Christianity is an exclusive religion. It is a militant, proselytizing, persecuting religion, in which it differs wholly from Confucianism, Shintoism and Buddhism. If there was any danger that China would have to pass through the ordeal of blood to which Europe has been subjected by Christianity since the middle ages there would surely be grounds for grave apprehension. The Crusades, the Thirty-years War, and the Spanish Inquisition, would be trifles compared to the fanaticism of the whole vast Chinese population, should it ever be seized with the spirit that actuated Europe during six centuries of its unhappy history. If any hope is to be expressed, it should be that there may never be an "official religion" in China, but if there is to be such, let it be one of those tolerant, peaceful and rational forms, that harmonize with all others, permit free discussion and work to the advancement of all moral, material, intellectual and spiritual development.

Of this book, perhaps more than of most others, is the trite remark of the perfunctory reviewer true, that it must be read to be appreciated. The above is not a review of it, but merely a brief mention of a few of the most vital points contained in it. The book is a study in sociology by a leading sociologist, based on direct personal observation, of the numerically greatest people on the globe.

LESTER F. WARD

BROWN UNIVERSITY,
PROVIDENCE, R. I.

Natural History of the American Lobster. By FRANCIS HOBART HERRICK, Ph.D., Sc.D. Document No. 747, from the Bulletin of the Bureau of Fisheries, Vol. 29, 1911. Government Printing Office, Washington, D. C.

There is surely no one acquainted with Professor Herrick's earlier monograph¹ on the lobster, who does not heartily welcome his recent book, "Natural History of the American Lobster."

¹"The American Lobster: A Study of its Habits and Development," *U. S. Fish Commission Bulletin*, Vol. 15, pp. 1-252.

Herrick's monograph of 1895 was an excellent assemblage of original data, bearing chiefly upon the anatomy and development—but to a very slight extent upon the habits—of our most far-famed decapod. The paper was adequately illustrated with original drawings and was accompanied by a bibliography of 213 titles. This was a book which merited a place upon the shelves of every zoologist and student of natural history—a place beside Professor Verrill's "Invertebrates of Vineyard Sound."

At the time of this earlier work, the lobster's main interest for the zoologist lay in the fact that it was an easily obtained "type-specimen"; gastronomically it was well known and appreciated, and the term, lobster, in the discussion of lobster laws, might sometimes have been heard in the halls of legislatures; that was about all. During the last fifteen years, circumstances have changed greatly. This species now finds itself at the focus of several zoological interests, and in legislative assemblies many word-battles have been fought in efforts to do equal justice to the lobster, on the one hand, and to the great American public on the other. The lobster fisheries of the country have become recognized as never before, as a point of great economic importance. The spirit of conservation, coupled with biological incentive, has rendered important the consideration of artificial propagation of marine fauna—a movement in which the propagation of the lobster has been foremost. But in addition to all this, the lobster has become possessed of more subjective interests. Important and instructive as has proved its developmental history, it has become a means of attack upon larger problems. As a subject for the study of regeneration and problems in morphogenesis, the lobster has supplied valuable material; and metamorphic transitions in cellular and tissue elements have been more clearly revealed through histological researches upon this invertebrate. Moreover, the student of animal behavior, a branch of study which, at the time of Herrick's earlier report, had scarcely emerged from the general field of nat-

ural history, has found in this crustacean a subject of value with reference to the investigation of problems in comparative psychology, instinct and habit-formation in lower animals. Both in this country and in Europe, many eyes have been turned upon *Homarus* and during the past six or eight years, alone, several important contributions based upon the study of this crustacean have been made. Indeed, as Herrick states, there is probably at the present time no invertebrate in the world better known than the American lobster.

Such a growing interest in *Homarus* can readily explain why it is that in Herrick's new publication we find 408 pages as compared with 252 in his earlier report; and why the bibliography has expanded from 213 to 329 titles. But this increased outside interest in the lobster does not account entirely for the greater proportions of the present work, since the author himself, through his continued studies, has added much, both in the text and in valuable illustrative features.

The subject matter of the book is presented in twelve chapters, which have the following headings: (1) The Lobsters and Allied Crustacea; their Zoological Relations, Habits, Development and Use as Food; (2) The American Lobster; its Economic Importance and General Habits; (3) Giant Lobsters; (4) Molt-ing; (5) Enemies of the Lobster; (6) The Anatomy of the Lobster, with Embryological and Physiological Notes; (7) The Great Forceps, or Big Claws; (8) Defensive Mutilation and Regeneration; (9) Reproduction; (10) Development; (11) Behavior and Rate of Growth; (12) The Preservation and Propagation of the Lobster.

The text of these chapters has been practically rewritten and many valuable additions have been made. These additions relate to chapter I., with its section on the "natural history of the Crustacea," to chapter VI., with the much more complete references to the internal anatomy, especially of the nervous system and its connections; to chapter VII., with its added sections discussing symmetry, asymmetry and torsion, data largely supplied by Herrick's recent investigations;

to chapter VIII., with fundamental additions to our knowledge of the regenerative process, and embodying the excellent work of Emmel; to chapter XI., bringing in an almost new section concerning the behavior of the lobster; and, finally, to chapter XII. (and also to part of chapter I.) discussing the economic importance of the lobster fisheries in this country and considering means of preservation and propagation.

In this last chapter, Herrick frankly considers the question, "What is the matter with the lobster?" and discusses very fully the pros and cons of all methods, legislative and otherwise, suggested for its protection. "Unfortunately for many years," says the author, "we have watched this race decline until some have even thought that commercial extinction, and that not far remote, awaited the fishery. . . . If this is primarily a scientific question, the zoological history of the animal should give us the answer. . . . The main biological facts . . . are now well in hand, and excuse can no longer be offered on the ground of ignorance."

After showing by means of convincing statistics the fact of the decline in the lobster fishery in this country, Herrick considers the cause.

More lobsters have been taken from the sea than Nature has been able to replace by the slow process of reproduction and growth. In other words, man has been continually gathering in the wild crop, but has bestowed no effective care upon the seed. The demands of a continent steadily increasing in wealth and in population have stimulated the efforts of dealers and fishermen, who must work harder each year for what they receive in order to keep up the waning supply. The natural result has followed, namely, a scarcity of numbers and a decrease in the size of the animals caught, with steadily advancing prices paid for the product. This is precisely what we should expect, had we based our judgment upon any sound principles of common sense and human economy, not to speak of a knowledge of the mode of life and general natural history of the animal in question.

Herrick shows that all measures which have heretofore been adopted in this country to

check the decline have failed, and it can be concluded that "either the laws are defective or the means of enforcing them are insufficient." Since a *closed season* for any animal, to have protective value, must correspond with the breeding season, and since this is impossible in the case of the female lobster (which spawns only once in two years and carries its eggs externally for about a year), closed seasons are not recommended as a possible means of improving conditions.

Moreover, legislation calculated to protect the "berried" lobsters has not been successful, because many fishermen evade the law by combing the eggs from the abdomen of the female. In addition, Herrick clearly points out that, even if an egg-loster law could be enforced, the protection aimed at must necessarily be reduced by one half, since the adult females lay eggs but once in two years, and therefore, at any given time only one half of them would be "in berry." The plan sometimes followed, of enclosing the "berried" females in crates and allowing the eggs to hatch naturally, Herrick thinks commendable, but inadequate for the preservation of the fishery.

As to the gauge law, while admitting that it has scarcely ever been thoroughly enforced in any locality, Herrick also believes this to be inadequate, whether short lobsters are destroyed or not.

First, by legalizing the capture of the large adult animals, above 10½ inches in length, we have destroyed the chief egg-producers, upon which the race in this animal, as in every other, must depend. Second, as supporting or contributory causes, some of us now, like others in the past, have entertained false ideas upon the biology of this animal, especially (a) upon the value of the eggs or their rate of survival, that is, the ratio between the eggs and the adults which come from them, and (b) of the true significance to the fisheries of the breeding habits, especially in regard to time and frequency of spawning and the fosterage or carriage of the eggs. Our practises have been neither logical nor consistent, for, while we have overestimated the amount of gold in the egg, we have killed the "goose" which lays it. We have thought the eggs so valuable that we have been to great

trouble and expense in collecting and afterwards hatching them and committing the young to the mercy of the sea, while we have legalized the destruction of the great source of the eggs themselves—the large producing females.

And again Herrick states:

This race needs eggs, not by the tens of thousands merely, but by the tens of billions, and it must have them or perish. Moreover, it can get them only, or mainly, through the big producers, the destruction of which the present gauge laws have legalized. If the lobster is a good incubator, the sea is a very poor nursery.

Thus Herrick brands as thoroughly ineffective any gauge law which protects the female lobster merely to the 9, 10 or 10½ inch limit. This limit enables them to lay, in all probability, but a single lot of eggs, usually not more than 10,000, and, according to Herrick's estimate, only one lobster out of 15,000 eggs reaches maturity.

Analyzed in the light of the law of survival (one out of 15,000 eggs), Herrick does not look upon the showing of the lobster hatcheries as very encouraging, since, to hold the lobster fishery at an equilibrium would require the hatching of larvae by the trillions; we can not work on such a scale. In the method of rearing the young through the critical or larval period, as practised at the Wickford Experiment Station of the Rhode Island Commission of Inland Fisheries, Herrick, however, sees great possibilities of material aid to the lobster fishery.

The chapter on Preservation and Propagation concludes with a set of five recommendations devised to protect the lobster fishery. These are worth presenting in full:

1. Adopt a double gauge or length limit, placing in a perpetual close season or protected class all below and all above these limits. Place the legal bar so as to embrace the average period of sexual maturity, and thus to include what we have called the intermediate class of adolescents, or smaller adults. These limits should be approximately 9 inches and 11 inches, inclusive, thus legalizing the destruction of lobsters from 9 to 11 inches long only when measured alive. In this way we protect the young as well as the larger adults, upon which we depend for a continuous supply of eggs. The

precise terms of these limits are not so vital, provided we preserve the principle of protecting the larger adults.

2. Protect the "berried" lobster on principle, and pay a bounty for it, as is now done, whether the law is evaded or not, and use its eggs for constructive work, or for experimental purposes with such work in view.

3. Abolish the closed season if it still exists; let the fishing extend throughout the year.

4. Wherever possible, adopt the plan of rearing the young to the bottom-seeking stage before liberation, or cooperate with the United States Bureau of Fisheries or with sister states to this end.

5. License every lobster fisherman, and adopt a standard trap or pot which shall work automatically, so far as possible in favor of the double gauge, the entrance rings being of such a diameter as to exclude all lobsters above the gauge, and the slats of the trap of such a distance apart as to permit the undersized animals to escape.

If the double gauge should prove ineffectual because of not being uniformly adopted or rigidly enforced, Herrick recommends the following steps with reference to the maintenance of the present laws:

1. Raise the legal gauge to 10½ inches wherever it now stands below this limit.

2. License every lobster fisherman, and adopt a standard trap, with slats of sufficient distance apart to permit the undersized lobsters to escape.

3. Destroy the enormously destructive interstate commerce in short lobsters.

4. Do not turn another larval lobster into the sea, but devote the energy expended in lobster hatcheries to rearing these young to the bottom-seeking stage after the methods now successfully practised at Wickford, R. I.

To conclude, it may be said that this volume on the American lobster is written in a clear and fascinating style, by virtue of which it will find approval in the hands of many classes of readers. To the scientifically minded it will be a mine of information, exact, well-classified and marvelously complete; to the ordinary reader it will prove an entertaining essay and study in natural history, while to those especially interested in the preservation and propagation of the lobster, it should serve as a trustworthy guide

for adequate legislation and for effective control of the lobster fishery.

PHILIP B. HADLEY

KINGSTON, R. I.

Farmers of Forty Centuries, or Permanent Agriculture in China, Korea and Japan.

By F. H. KING, D.Sc. Published by Mrs. F. H. King, Madison, Wis. 8vo. Pp. 441, 248 illustrations. 1911.

A more wholesome work at the present stage in agricultural agitation in this country could scarcely be written; nor could it well come from one better fitted to write it, for the tenor of the story falls closely into line with Professor King's intensive studies on soil management. In a very peculiar sense the art of soil management in distinction from soil science constitutes the theme of this work. Until recently, the Chinese, Japanese and Koreans were almost wholly without formal agricultural science in the western technical sense, while they have for centuries been adepts of unsurpassed skill in agricultural practise. The story of Professor King is not the less weighty because he has seemed to lean a little at times to the tide of Occidental opinion that has set rather strongly heretofore toward chemical analysis as the decisive mode of attack and source of guidance, and he can not be thought partial in setting forth the attainments of Oriental peoples who have worked in almost entire negligence of all resources but those of the farm, the home and the town. "Farmers of Forty Centuries" is in effect a sketch of domestic methods of nursing crops.

As Dr. Bailey intimates in a graceful preface to the book, Dr. King has played well the rare part of "an agricultural traveler" and his results are quite on the high level of those other traveling experts who set forth natural features or social phenomena with expert touch. Professor King crossed Japan and touched eastern China on his inward trip, but his serious work only commenced when he reached the tropical border of south China and began to work northward with the advancing season. This put him in the way of critically following the modes of treatment in

vogue just at the transition from the winter crops to the spring and early summer crops. These combined at once the maturing and the harvesting of the one and the fitting, the planting and the early culture of the other. Thus he advanced by stages—looping back for restudy midway—from the tropical border in Kwangtung and Kwangsi, into Chekiang and Kiangsu in the latitude of our southern states, later into Shantung and Chili in latitudes comparable to Kentucky and Illinois, and at length into Manchuria, whose climate is comparable to that of our distinctly northern states. Passing through Korea, he was guided in a further study of Japan by details from the Japanese agricultural stations in which western science has already joined hands with Oriental experience with the happiest results.

King's treatment is everywhere sympathetic and appreciative. He is singularly free from the Occidental provincialisms that mar so many stories of Oriental travel. He seems to have carried at all times the trained sense of the agriculturalist and of the student of fertilization, not the sniffing nose of the typical westerner. He seems in no wise to have been squeamish about inevitable organic odors, but yet was keen enough to note the singular scarcity of flies and to draw the inference that it meant a vital order of cleanliness and carried a sanitary significance. In the universal use of hot tea-tinctured drinks he saw as other incisive travelers have done an important protective custom. Nowhere does he lapse into grewsome pictures of putative decimations due to invited diseases. His tale is that of a fair-minded friendly visitor seeking to learn, and his story is in grateful contrast to the irksome animadversions of the commonplace Occidental writer who plumes himself on looking down on Oriental customs "e superi-ore loco," as Cæsar would say.

King's statements are larded with quantitative data and carry a wealth of precise fact brought close home to the special cases of individual farmers or particular practises. The smallness of the farms, the largeness of the product, the lavishness of the labor and a multitude of special items relative to specific

crops, modes of handling, costs of fertilization, and largeness of population per unit area, make the book a thesaurus of its kind.

The author, like the reviewer whose educational studies in China ran contemporaneously with these agricultural ones, was impressed with the extent of resources still unused in the very regions whose overcrowded condition has been so common a theme of lugubrious comment. Scattered through the volume there are economic points of the most vital pith that should serve as an antidote to the pessimistic Jeremiads so current in these days and so commonly floating on very shallow waters. The following quotation from the final chapter on Japan, p. 425, must suffice to indicate the tenor of the author's outlook on future possibilities:

In 1907 there were in the [Japanese] Empire some 5,814,362 households of farmers tilling 15,201,969 acres and feeding 3,522,877 additional households, or 51,742,398 people. This is an average of 3.4 people to the acre of cultivated land, each farmer's household tilling an average of 2.6 acres.

The lands yet to be reclaimed are being put under cultivation rapidly, the amount improved in 1907 being 64,448 acres. If the new lands to be reclaimed can be made as productive as those now in use there should be opportunity for an increase in population to the extent of about 35,000,000 without changing the present ratio of 3.4 people to the acre of cultivated land.

While the remaining lands to be reclaimed are not as inherently productive as those now in use, improvements in management will more than compensate for this, and the Empire is certain to quite double its present maintenance capacity and provide for at least a hundred million people with many more comforts of home and more satisfaction for the common people than they now enjoy.

The soul of the book lies in its appreciative delineation of methods that have sufficed for the maintenance through many centuries of perhaps the highest average productivity ever attained by great peoples, and its chief lesson lies in the realization of this by simple domestic means. The style of the book is excellent and the two hundred and forty odd half tones effectively illustrate the text.

That this should be the last contribution of one who has written so much and so well is a source of inexpressible regret.

WHEAT RUSTS AND SUNSPOTS

IN looking over a copy of the *Journal of the Agri-Horticultural Society of Western India* for April to June, 1906, I was interested to notice, on page 165, an article with the above caption, by G. N. Sahasrabudhe, of the College of Agriculture at Poona. The author refers to a report in the *Proceedings of the Australian Wheat Conferences* of periodicity in the occurrence of *Puccinia graminis* in Australia. The years of the most severe attacks, it is stated, were 1867, 1878 and 1889, making a period of eleven years between every two maximum years. The writer goes on to state that this cycle suggested to some members of the conference that it had some relation with the various phases through which the fungus has to go, but quotes from Surgeon-Major D. Prain the statement that "the periodicity is not due to any inherent property of the fungus, but must, as seems to be the belief in Chili, be due to the recurrence of conditions favorable for its development."¹ I quote the following paragraph entire:

We have trustworthy records of rust attacks in Australia from 1867. In that year it was almost

general and caused immense loss in South Australia. This is the minimum year of the sun-spot cycle (1867-78). The year 1878 was one of the worst years for rust in Victoria, and in South Australia it prevailed over a large area that year; that also was the minimum year of the sun-spot cycle. In South Australia 1880 was the year when a considerable area was affected; and it was the year when the sun-spot area was very small. The seasons 1882-1888 seem to have been very free from rust; and that was the maximum period of the sun-spot cycle (1879-1889). In 1889 it was almost general and caused great loss in South Australia, Victoria, New South Wales and Tasmania; and that was the minimum year of the sun-spots. This clearly proves that the attack of the pest is most severe when the sun-spot area is the smallest, and from the theory of the sun-spots it does not seem unnatural. It is well known that the changes in sun-spots are closely related to the changes in the atmospheric pressure and consequently in the rainfall; and experience shows that the development of the fungus is dependent to a great extent on the atmospheric conditions and rainfall. The opinions of the farmers put forward in the Second and Third Conferences indicate the same thing. Rust is usually most prevalent in seasons when the rainfall is excessive, especially during October and November.² When close, damp, muggy weather sets in, the rust is certain to appear (indicating diminution in pressure). A dry cold season in Queensland is inimical to rust. The year 1889, which was a very rusty one, was marked in New South Wales by frequent thunderstorms at the time the wheat was in bloom. The colder districts were in that year less rusty than others.

The author states that when he thought the matter over, especially the remark by Dr. Prain, he thought there must be some relation between this eleven-year cycle and the Brookner's cycle of sunspots, which is also of eleven years, and that when he began to compare the two cycles closely, he was "almost convinced" that there must be some relation between sunspots and the growth of the *Puccinia* fungus. This relationship, he concludes, may "throw a great light on the life history of the fungus and also we may be able to foretell the years in which the rust attacks will

¹ Agri. Ledger, No. 16 of 1897, p. 9.

² Proc. of II. Con., 17, 49.

be severe from the observation of the sun-spots."

A hasty survey of the literature concerning the occurrence of *Puccinia*, and brief correspondence or personal conferences with some of our American botanists failed to reveal any knowledge of this hypothesis, and although it is not probable that it is of any great importance, I thought it would be of sufficient interest to be placed on record in an American publication. C. STUART GAGER

BROOKLYN BOTANIC GARDEN

SPECIAL ARTICLES

TIER-LIKE ARRANGEMENT OF THE ELEMENTS OF CERTAIN WOODS

THERE are numerous woods which present on longitudinal section (particularly the tangential) fine, delicate cross lines or stripes sometimes called "ripple marks." The distance between these markings varies from 0.11 to 0.50 mm., and is fairly constant for a species. On some woods (*e. g.*, *Esculus octandra* Marsh., *Swietenia mahagoni* Jacq., *Bombax insignis* Wall. and *Pterospermum diversifolium* Blume.) these lines are very clear and distinct to the unaided eye; on others (*e. g.*, *Tilia americana* L., *T. pubescens* Ait., *Pterocarpus indicus* Willd. and *P. dalbergioides* Roxb.) they are near the limit of vision or again (*e. g.*, *Guaiacum sanctum* L. and *G. officinale* L.) they are invisible without the lens. In most species showing these markings the feature is constant and of considerable importance for diagnostic purposes, though in a few species (*e. g.*, *Swietenia mahagoni*) the same piece of wood may show the markings in one place and not in another.

This cross-striping of a wood is due (1) to the arrangement of the rays in horizontal series, or (2) to the tier-like ranking of the wood fibers, vessel segments or other elements, or (3) to a combination of (1) and (2). The lines resulting from the horizontal seriation of the rays is usually more conspicuous and of more common occurrence than those in (2). In the combination of the two forms, which is very common, the junction of the vessel

segments or of the fibers is usually between the rays.

This peculiar arrangement of wood elements is also evidenced on transverse section. Where the rays are in perfect horizontal seriation a section between two tiers shows an entire absence of rays. In most instances, however, it results in gaps of irregular width depending upon the regularity of the stories. Where the rays are much wider near the middle than at the margin their apparent width when viewed transversely will show considerable variation, according to the relative location of the plane of section. Where the fibers are arranged in tiers their apparent size is affected in a similar manner. According to von Höhnell¹ the fibers in *Bocoa provocensis* Aubl., and a few other tropical woods with cross-striping are also radially disposed, and when the plane of cutting passes near the junction of two tiers the section shows large and small cells in alternate radial rows. The small cells are sections of the tips of the fibers forced by growth between their upper and lower neighbors. It is von Höhnell's theory that their appearance in alternate radial rows instead of alternately in the same row is the result of the pressure of the bark upon the cambium while the fibers were being formed.

Tier-like arrangement is most common in tropical woods and has been found fairly characteristic of the families Casalpiniaceæ and Zygophyllaceæ. Various writers² have

¹ Von Höhnell, Franz Ritter, "Ueber stockwerk-artig aufgebaute Holzkörper," *Sitzungsberichte der Mathematisch-Naturwissenschaftlichen Classe der kaiserlichen Akademie der Wissenschaften*, Vol. 89, Part 1, Wien, 1884, pp. 30-47. Von Höhnell, Franz Ritter, "Ueber den etagenförmigen Aufbau einiger Holzkörper," *Berichte der Deutschen Botanischen Gesellschaft*, Vol. II., Berlin, 1884, pp. 2-5.

² Flückinger, J. A., "Pharmacognosie der Pflanzen," 2d ed., pp. 463, 466. Wigand, A., "Anatomische Atlas zur pharmaceutischem Werk-ende," 1865, tables 26, 27. Whitford, H. N., "The Forests of the Philippines," Bul. 10, Bureau of Forestry, Manila, P. I., 1911, Vol. II., p. 36.

called attention to this feature which is especially striking on red sanders (*Pterocarpus santalinus* L. f.), narra (*P. indicus* Willd.), and Jamaica quassia (*Picrasma excelsa* Planch.). Von Höhnel (*loc. cit.*) observed it in about 80 different woods, all tropical or sub-tropical but one (*Diospyros virginiana* L.), and most of them unidentified. His list of the identified woods includes 35 genera of 12 families, viz., Cæsalpiniaceæ, Papilionaceæ, Mimosaceæ, Zygophyllaceæ, Böttneraceæ, Malvaceæ, Cedrelaceæ, Bignoniaceæ, Simarubaceæ, Ebenaceæ, Rosaceæ and Sapindaceæ.

Included in v. Höhnel's list are two species which occur in the United States, viz., *Swietenia mahagoni* and *Diospyros virginiana*. In addition to these two the present writer has observed tier-like arrangement in the woods of *Æsculus octandra*, *Tilia americana*, *T. pubescens*, *T. heterophylla* Vent. and *Guaiaecum sanctum*.

ÆSCULUS (BUCKEYE)

In the wood of *Æsculus octandra* the rays are fine, uniseriate, uniform, inconspicuous, mostly 10-12 cells high, measuring about 0.25 mm. The average distance between the rays is, vertically, 0.15 m.; laterally, 0.06 mm. Their arrangement is in horizontal series, very regular on the radial section but forming somewhat wavy lines on the tangential, though always plainly visible to the unaided eye. The vessel segments are from 0.35 to 0.40 mm. long and are in series, the horizontal planes of their perforations alternating with the rays. The fibers appear not to be in storied arrangement.

The cross-markings on tangential surface are characteristic of *A. octandra* and were not observed in *A. glabra* Willd., *A. californica* Nutt. or *A. hippocastanum* L., though all three show indistinctly on radial surface a tier-like arrangement of the wood elements. This feature is thus important in separating the wood of *A. octandra* from others of the genus.

TILIA (BASSWOOD)

Tier-like arrangement of the wood elements is characteristic of the woods of *Tilia ameri-*

cana, *T. pubescens* and *T. heterophylla*. The ending of the vessel segments, wood fibers and wood parenchyma fibers is quite uniform. The rays are widely variable in size and are irregularly spaced. The small rays are uniseriate and mostly 10-15 cells high; the largest are 3-5 cells wide and 50-100 cells high. The cells are small and much flattened laterally.

The cross-markings of *Tilia* are not conspicuous, but in proper light are usually readily visible to the unaided eye. The average height of the tiers is about 0.40 mm.

SWIETENIA (MAHOGANY)

Tier-like arrangement is often characteristic of the true mahogany (*Swietenia mahagoni*). While it may be absent, it is quite often very conspicuous. When present the tiers vary in height from 0.35 to 0.50 mm. The rays are deep crimson in color, fusiform, and quite irregular in size; 1-5, mostly 2 or 3, cells wide, and 4-20, mostly 10-15, cells high. When the rays are in storied arrangement they coincide with the vessel segments.

Swietenia senegalensis Deso. is said by von Höhnel (*loc. cit.*) to be without cross-stripping.

DIOSPYROS (PERSIMMON)

In *Diospyros virginiana* the rays are very numerous, composed of large cells in 1-2 (rarely 3) rows, and from 2-14, usually 10-12, cells high. They are arranged in horizontal series which correspond with the vessel segments, wood fibers and wood-parenchyma fibers. The arrangement is often somewhat irregular and is never conspicuous, though clearly visible to the unaided eye. The height of the tiers is about 0.35 mm. The horizontal seriation of the rays appears to have been first described by Molisch.*

Available specimens of the wood of *D. texana* Sch. do not exhibit the cross-markings.

*Molisch, H., "Vergleichende Anatomie des Holzes der Ebenaceen und ihrer Verwandten," *Sitzungsberichte der Mathematisch-Naturwissenschaftlichen Classe der kaiserlichen Akademie der Wissenschaft*, Vol. 80, Part I., Wien, 1879.

GUAIAACUM (LIGNUM-VITÆ)

The wood of *Guaicum sanctum* exhibits very fine and quite uniform cross-markings, visible with the aid of the lens. The rays are very fine, uniseriate, mostly 5-7 cells high, deeply colored, appearing under lens like fine hachures. The height of the tiers varies from 0.15 to 0.18 mm. The scattered vessels are filled with a dark-colored resin which adds to their prominence. The vessel segments alternate with the rays.

Guaicum officinale L. is similar to *G. sanctum* in the arrangement of the wood elements. The distance between markings is often as low as 0.11 mm. The rays are about 0.05 mm. apart laterally and 90 μ vertically.

In addition to those mentioned above, the writer has observed many tropical woods (particularly African and Brazilian) with tier-like arrangement of their elements.

SAMUEL J. RECORD

YALE FOREST SCHOOL

A SCLEROTINIA ON APPLE

PRIOR to 1902 the fungus causing the brown rot of fruit, both drupaceous and pomaceous, was, at least in this country, commonly referred to *Monilia fructigena*. Norton¹ observed the perfect stage of the fungus on peach, and called it *Sclerotinia fructigena* (Persoon) Schroeter. Coincident with Norton's work on the *Sclerotinia*, Aderhold,² of Germany, was making a study of some forms of this genus and was able to secure a perfect stage of a *Monilia* on apple. He has published good evidence that the form of *Sclerotinia* he found on apples was *Sclerotinia fructigena* (Persoon) Schroeter, and that the form Norton found on peach was *Sclerotinia cinerea* (Bon.) Schroeter instead of *S. fructigena*, although this name has not since been taken up by American authors.

Aderhold was the first investigator to report the perfect stage of *Monilia* or brown rot

¹ *Trans. Acad. Sci. St. Louis*, Vol. 12, p. 91, 1902.

² *Ber. Deutsch. Bot. Land. Ges.*, Vol. 22, p. 267, 1904. Aderhold and Ruhland, *Arb. Biol. Abt. Land. Forst. Gesandh.*, Vol. 4, p. 29, 1905.

fungus on apple, and it has not, so far as I know, been reported since.

I have recently (November, 1911) obtained apothecia of *Sclerotinia* upon mummied apples, which were strikingly different in some respects from those described by Aderhold. These were produced by placing mummied apples in a greenhouse during April, 1911. The mummied fruits were lying upon the surface of the soil and were of course subjected to alternate wetting and drying. During the following summer the greenhouse was neglected and the mummies became very dry, which may to some extent account for the growth of the apothecia later on during the season. The sclerotia remained apparently dormant until a light heat was applied in the building during November. They were first observed by me November 13, 1911. The temperature in the greenhouse at this time was very similar to that of spring conditions, which, I think, was mainly responsible for the growth of the apothecia.

When collecting these decayed fruits only those were selected that were thought to have been grown two seasons previously. Of a dozen or more mummies placed in the greenhouse, all disappeared during the summer but eight; of these eight, five produced forty-one apothecia.

The apothecia arose from the characteristic sclerotia of this genus. The cups varied in size from one to four mm. across. When young they were decidedly campanulate, then flattening to a disk and later becoming cup-shaped again. In color they varied from a cinnamon-brown to gray, when mature.

The mummies were all lying upon the surface of the soil, therefore there was no necessity for a long growth of stipe. Its length ranged on the average from 1 to 2.5 mm. One stipe made a growth of one half centimeter.

In general, the parts of the apothecia are very similar to those growing upon peach, and also to those described by Aderhold as growing upon apple. The most striking dissimilarity is in size, the new form being much smaller.

The asci measure 44 to 64 microns long and

4 to 6 microns wide. The spores are oblong, somewhat pointed at both ends, 6 to 8 microns long and 2 to 3 microns wide. The paraphyses which are very numerous and which vary somewhat from filiform to clavate, are 40 to 60 microns long and 1 to 3 microns wide.

TABLE GIVING THE COMPARATIVE MEASUREMENTS OF THE PEACH AND APPLE SCLEROTINIAS

	Asci	Asco- spores	Para- physes	Apothe- cia	Stipe
Peach	89.3-10.26 μ by 5.9-6.8 μ	6.2-9.3 μ by 3.1-4.6 μ			3-5 cm. long
Apple (Demarree)	44-64 μ by 6-8 μ	6-8 μ by 2-3 μ	40-60 μ by 1-3 μ	1-4 mm. across	1-5 cm. long
Apple (Aderhold)	120-180 μ by 9-12 μ	11-12.5 μ by 5.6-6.8 μ	175-180 μ by 2-5 μ	1 mm. across	.5-15 cm. long

The above table shows very plainly the dissimilarity of the forms found by Aderhold and those found here. In every respect the different parts of the *Sclerotinia* are smaller than those described by the German investigator.

It is to be regretted that I was unable to produce any growth from the ascospores, though they were tried in various cultures, including fruit and cooked apples; therefore there is no proof of any connection with a conidial form of *Sclerotinia*. But it seems evident that this is a new *Sclerotinia*, although it may be, and it is my supposition that it is, the perfect form of the fungus causing the brown rot of apples in this country. It may, however, be the perfect stage of *Monilia uredoformis* Ellis & Everhart¹ which has been reported as growing upon apples. If so *Monilia uredoformis* Ell. & Ever. would be referred to *Sclerotinia* as *Sclerotinia uredoformis*, although it is very obvious that this can not be done until *Monilia* spores can be produced from the new form. The investigation of this *Sclerotinia* will be continued and I hope to be able to report something more definite later.

THE AMERICAN SOCIETY OF NATURALISTS

THE twenty-ninth annual meeting of the American Society of Naturalists was held in Guyot Hall of Princeton University on December 28.

The eastern and central branches of the American Society of Zoologists so arranged their program that members were enabled to attend the Naturalists' meeting. Many members of the Association of Anatomists, which also met at Princeton, attended the program. Although the Botanical Society met elsewhere, a number of botanists were present. It may fairly be said, judging from the attendance of the sessions, that the Naturalists' Symposium was the central feature of the entire Princeton meetings.

The Anatomists, Zoologists and Naturalists had a joint smoker at the Princeton Inn on Wednesday evening.

The Naturalists' dinner was given on Thursday evening at the Princeton Inn. More than one hundred persons were present, this being the largest attendance for a number of years. After the dinner the president, Professor H. S. Jennings, delivered his address on "Heredity and Personality." This splendid address was most enthusiastically received and has been published in the December 29th number of *SCIENCE*.

The scientific program of the meeting was given on Thursday, both forenoon and afternoon.

The forenoon meeting was devoted to a discussion of "The Relation of the Experimental Study of Genetics to the Problems of Evolution." The following papers were presented:

E. G. Conklin (Princeton University): The Problems of Evolution and the Ways they may be best Attacked.

C. B. Davenport (Carnegie Institution): Light thrown by the Experimental Study of Heredity upon the Factors and Methods of Evolution.

W. Johannsen (University of Copenhagen): Modern Exact Genetics in relation to the Problems of Evolution.

H. F. Osborn (American Museum of Natural History): Unit Characters, Continuity and Discontinuity, as observed by the Paleontologist.

H. L. Clark (Museum of Comparative Zoology, Harvard University): Pure Lines and Phylogeny.

At the afternoon session papers on Genetics were read as follows:

B. M. Davis (University of Pennsylvania): Further Hybrids of *Oenothera biennis* and *O.*

grandiflora that resemble *O. lamarckiana* (with demonstrations).

W. Johannsen (University of Copenhagen): *Some Mutations in Pure Lines of Beans.*

G. H. Shull (Carnegie Institution): *New Place Effects and the Genotype Concept.*

R. Pearl (Maine Agricultural Experiment Station): *On the Mechanism of Inheritance of Fecundity in the Domestic Fowl.*

T. H. Morgan (Columbia University): *Associative and Mendelian Inheritance.*

E. B. Wilson (Columbia University): *Some Problems of Cytology in relation to the Study of Genetics.*

D. H. Tennent (Bryn Mawr College): *The Correlation between Chromosomes and Particular Characters Exhibited in Hybrid Echinoid Larvæ.*

H. D. Goodale (Carnegie Institution): *Castration in relation to Secondary Sexual Characters in Brown Leghorns.*

R. K. Nabours (Kansas State Agricultural College): *Inheritance in the Grouse Locust (with demonstrations).*

H. J. Webber (Cornell University): *The Inheritance of Characters in Peppers.*

All of the papers read before the Society will appear in series in the forthcoming numbers of *The American Naturalist*.

The following were elected to membership in the Naturalists: Alice M. Boring, University of Maine; H. L. Clark, Harvard University; C. D. Congdon, Cornell Medical School; H. K. Hayes, Connecticut Agricultural Experiment Station; E. P. Humbert, New Mexico Agricultural Experiment Station; F. Payne, University of Indiana; H. D. Senior, New York University and Bellevue Medical College; L. H. Smith, University of Illinois; L. R. Waldron, North Dakota Agricultural Experiment Station.

The following officers were elected for 1912:

President—Professor E. G. Conklin, Princeton University.

Vice-president—Professor R. G. Harrison, Yale University.

Secretary—Professor A. L. Treadwell, Vassar College.

Treasurer—Professor W. E. Kellicott, Goucher College.

Additional Members of the Executive Committee—Professor B. M. Davis, University of Pennsylvania; Professor H. E. Jordan, University of Virginia.

CHAS. B. STOCKARD,
Secretary 1911

THE WASHINGTON MEETING OF THE AMERICAN CHEMICAL SOCIETY

AGAIN the American Chemical Society has held the largest meeting in its history, 658 members and guests registering in Washington, and probably 700 were present.

The meeting opened on Wednesday, December 27, with a joint meeting of the Section on Chemical Education and the Division of Physical and Inorganic Chemistry, at which the following four papers were given:

A. A. Noyes (chairman): *The Teaching of Physical Chemistry.*

W. D. Bancroft: *Physical Chemistry in the Introductory Course.*

H. C. Jones: *The Introduction of Physical Chemical Conceptions in the Early Stages of the Teaching of General Chemistry.*

J. Howard Mathews: *Some Applications of Color Photography in the Teaching of Physical Chemistry (illustrated).*

In the afternoon the address of Vice-president Frankforter, of Section C, entitled "The Resins and their Chemical Relations to the Terpenes," was delivered before a large audience and was followed by an address by Chairman H. P. Talbot on the subject "Privileges and Responsibilities of the Chemical Analyst." Following Dr. Talbot, Dr. A. L. Voge, of the Library of Congress, read a paper on "Ostwald's Proposed International Institute of Chemistry."

Throughout the week the society's Divisions of Agricultural and Food Chemistry, Biological Chemistry, Industrial Chemists and Chemical Engineers, Fertilizer Chemistry, Organic Chemistry, Pharmaceutical Chemistry, Physical and Inorganic Chemistry and the Chemistry of India Rubber, held meetings in rooms especially assigned to them.

Some 500 were present at the "smoker" on Wednesday evening, which was fully up to the standard of the well-known smokers of the Chemical Society.

On Thursday evening Alexander Smith, president of the society, delivered his presidential address, entitled "An Early Physical Chemist," and was followed by an interesting lecture by Frank B. Kenrick and H. E. Howe, consisting chiefly of illustrations by means of the lantern of the effect of temperature, pressure, concentration, surface tension, osmotic pressure, etc., on reactions in heterogeneous systems.

A feature of the divisional meetings was the

Symposium on Mineral Wastes and their Conservation, held before the Division of Industrial Chemists and Chemical Engineers on Friday. The following papers were presented and the discussion was prolonged throughout the day:

J. A. Holmes: Carbon Waste.

W. H. Bassett: (a) Zinc Losses in Brass Manufacture; (b) Need of Special Alloys for Special Uses.

W. R. Whitney: New Uses to Reduce Abuses in Conservation.

A. V. Bleining: Wastes in the Ceramic Industry.

A. D. Little: The Abuse of Brand.

F. K. Cameron: Waste and Conservation of Potash and Phosphoric Acid.

F. G. Cottrell: Sulphur Fumes and Flue Dust.

Charles L. Parsons: Miscellaneous Mineral Wastes.

This program, together with the papers given, will be featured in the March *Journal of Industrial and Engineering Chemistry*.

The Division of Pharmaceutical Chemistry held a Symposium on Drug Assaying on Friday morning and on Friday afternoon a joint meeting of the Society of Biological Chemists was held with the biological chemists of the American Chemical Society.

The secretary's report showed an increase of members of over five hundred for the year, the society's membership standing on December 1 at 5,603. During the year the society spent over \$55,000 on its journals, returning to each paid member in actual cost of publications more than 100 per cent. of his dues.

At the meeting of the council on Tuesday afternoon and evening the Biological Section of the society was authorized to form a Biochemical Division, electing its own officers, and two new local sections were formed; one at Detroit and one at New Haven.

Interesting reports were received from the Committee on Standard Methods of Analysis and from the Committee on Patent and Related Legislation.

It was voted to donate the library of the American Chemical Society to the New York Chemists' Club on condition that members of the Society have ready access thereto.

The question of the time of the annual meetings of the society was vigorously discussed, many members favoring a change from the winter season to Easter week, and a committee was appointed to take this into consideration and report to the council.

The election of the following officers was announced for 1912:

A. D. Little, President; C. L. Parsons, Secretary; A. P. Hallock, Treasurer; W. A. Noyes, Editor of the *Journal of the American Chemical Society*; A. M. Patterson, Editor of *Chemical Abstracts*; M. C. Whitaker, Editor of the *Journal of Industrial and Engineering Chemistry*; E. G. Love and Alexander Smith, Directors for two years; S. W. Parr, W. H. Walker, W. L. Miller and W. D. Bigelow, Councilors-at-Large for three years; C. H. Herty, Councilor-at-Large to fill the unexpired term of A. D. Little; E. G. Love, G. C. Stone and A. E. Hill, Finance Committee; Wm. McMurtrie, C. L. Parsons and B. E. Curry, Membership Committee.

Over two hundred and fifty papers were presented at the meeting, abstracts of many of which will appear shortly in *SCIENCE*.

CHARLES L. PARSONS,
Secretary

THE AMERICAN PHYTOPATHOLOGICAL SOCIETY

THE third annual meeting of the American Phytopathological Society was held in Washington, D. C., December 27-29, 1911, in affiliation with the American Association for the Advancement of Science. A program of fifty-one papers was presented. Joint sessions with Section G and also with the Botanical Society of America were held. The present membership is about 240. The report of the business manager of *Phytopathology*, the official organ of the society, showed a small balance to the credit of the journal after all the expenses for the first volume had been paid. The present editorial staff and business manager of the journal were continued for the coming year. The following are the officers for 1912:

President—G. P. Clinton, Agricultural Experiment Station, New Haven, Conn.

Vice-president—F. C. Stewart, New York Agricultural Experiment Station, Geneva, N. Y.

Secretary-Treasurer—C. L. Shear, U. S. Department of Agriculture, Washington, D. C.

Councilors—W. A. Orton, U. S. Department of Agriculture, Washington, D. C.; Erwin F. Smith, U. S. Department of Agriculture, Washington, D. C.; A. D. Selby (*ex officio*), Ohio Agricultural Experiment Station, Wooster, Ohio; L. R. Jones (*ex officio*), University of Wisconsin, Madison, Wis.

THE STATUS AND FUTURE OF THE AMERICAN AGRONOMIST¹

ON the occasion of this fourth annual meeting of the American Society of Agronomy it is of interest to note that our membership has now grown to more than two hundred and that our published proceedings are finding their place not only in the private libraries of American agronomists, but also on the shelves of the libraries of the leading colleges and universities of the country. Indeed the time seems to have arrived when this society should seriously consider supporting a journal. We have definitely put our hands to the plow. It behooves us, therefore, to be diligent, to push this society into the front rank of the scientific societies of the land, and to guard jealously against any and all influences which may interfere with the highest development of its individual members and thereby restrict its opportunity for public usefulness.

It must be recognized that no scientific body can be brought to its highest plane nor be made of the greatest service to our American people unless the ideals of its individual members are high. The future of agronomy in this country is, however, not only dependent upon such ideals, but also, in a very great degree, upon the administrative attitude of the institutions which we serve.

To the professor who, a generation ago, was covering in his way the whole range of agricultural science, the field of the present-day agronomist may seem narrow; but those who have kept pace with the march

¹ Presidential address before the American Society of Agronomy, November 13, 1911.

of recent events must be impressed with its breadth and by the fact that even greater specialization is foreshadowed in the near future, when the subject of agronomy may readily resolve itself into several distinct fields of effort.

The student of farm crops can no longer be content with a knowledge of what belongs to the art of crop production, but must now be well grounded in systematic botany, especially in its relation to the bacteria and fungi, and to the plant families which embrace the weeds, grasses and the common farm crops. He should understand and follow the work in breeding which is being done throughout the world.

In order to deal with many of the problems with which he will be confronted as an investigator and which he should be able to fully grasp as a teacher, fundamental training in physiological botany becomes essential. Indeed, this is only the beginning, for the agronomist has not only to deal in detail with the plants which contribute directly to the food supply of man and of our domestic animals, but also with an extensive soil flora almost undreamed of a half century ago, upon the study and control of which, for the furtherance of agriculture, the world is to-day barely entering. The agronomist of the future must not only deal with the effect of these soil plants upon each other and upon the higher plants in their parasitical and symbiotic relations, but also as producers of ammonia and nitrates, and as destroyers of compounds of sulfur and of nitrogen within the soil.

As suggested by the recent investigations of soil amebæ by Hall and his co-workers at Rothamsted, he must also deal with microscopic animal denizens of the soil which may militate against, or, as perhaps may yet be found, aid in the growth of certain beneficial fungi, and other micro-

scopic flora. In fact, the end is not yet, for chemistry now plays its rôle in furnishing the agronomist carbon bisulfide, and other substances for combating unfavorable animal life in the soil. Chemistry also plays its part in controlling and regulating the chemical reaction, and hence the dominance or decadence of various types or even of individual representatives of the soil flora.

There is reason to believe that we are to-day but entering upon the study of the organisms and of the conditions best suited to ensure the assimilation of atmospheric nitrogen by non-symbiotic means.

The whole question of the use of fertilizers and of their action is daily becoming more complex. It was a simple proposition when one supposed that it was merely essential to learn what elements crops removed from the soil and then to supply a proper part thereof, without special reference to the particular compounds used to supply them. To-day, cognizance must be taken of the effect of the associated compounds. The sulfuric acid and chlorin combined with ammonia in ammonium sulfate and ammonium chlorid may have a highly toxic effect from the outset, or such effects may soon develop in certain soils if care is not taken to maintain a proper basic condition. The subsequent effect of organic nitrogenous manures is quite different on some soils from that of nitrate of soda. Even though the avoidance of chlorin and sulfuric acid, when combined with ammonia, is of vital importance under certain circumstances, it is often less necessary under the same conditions if they are in combination with potassium, calcium and magnesium. For still other crops, or on another soil, they may nevertheless be used with good effect.

Another illustration is afforded by nitrate of soda. The residual effect of re-

peated annual applications may result in the most marked soil improvement, rendering successful the cultivation of a whole series of crops where they could not be grown successively before. The same treatment, even for a long series of years, may still fail to correct the existing soil conditions enough for other groups of plants. The continued use of nitrate of soda on another soil may cause it to become puddled until it is rendered practically unfit to be a habitat for most agricultural plants. For certain plants, such as the radish and beet, the residual sodium from nitrate of soda may perform valuable physiological functions which would be lacking, or of slight importance, in connection with certain other plants. Raw rock phosphate may be valuable as a fertilizer on the black soils of the Illinois corn-belt and for crops usually grown there, but for the light sandy soils of the Atlantic coast and for certain trucking crops its use at prevailing prices could perhaps not be recommended. To add to this complexity certain text-books proscribe the use of lime with superphosphates, or on soils where undissolved phosphates are to be used, and yet there may be soils on which liming is essential to the most economical use of each. It is, in fact, not enough that the agronomist should bear in mind and master all of these details, but now he is called upon to consider the specific requirements for lime and other substances, of hundreds of varieties of plants. He must also consider the alleged toxic root excreta and methods for rendering them innocuous, and he must take cognizance of the catalytic action of manganese and other elements not heretofore grouped in the galaxy of fertilizers and soil amendments. He must now consider the effect of legumes and other plants upon those growing in association with them and the effect

of given crops upon those which follow. The whole question of maintaining conditions favorable to nitrification is of prime importance in certain sections of the United States, and in this connection chemistry is again the handmaid of agronomy; yet in certain of the semi-arid regions of the middle west excessive nitrification is said to have become a scourge which is wiping out many of the most promising orchard industries. It must be evident that the agronomist must therefore be something of a climatologist, for in certain of these features the weather conditions are the chief governing factors.

The successful agronomist must also deal effectively with a host of plant parasites which may attack the roots, the base of the stems, or the other aerial parts of the plants. Some of these may be killed by poisons, whereas others can not. Even the sucking and boring insects furnish a problem in themselves, long after the entomologist has determined the essential features of their life history. Just as "every animal has its fleas and these have fleas to bite 'em," so the plants have their many animal and fungus parasites, with which the agronomist is forced to deal.

Since the soil is one of the chief concerns of the agronomist, and it is known to be teeming with many forms of microscopic life of beneficial or injurious character, it is important to take cognizance of the possible effect upon this life of the various kinds of organic matter and of fertilizers which may be introduced into the soil from time to time.

Notwithstanding the recent assertion that practically the same minerals are found in all soils, that plants feed from very weak solutions, and that the soil solution is being continually renewed, we cannot complacently fold our arms and watch the workings of the divine providence in

the production of food for the human race; for some soils appear still to lack enough available plant food at certain stages of growth, and others give rise to conditions, naturally, which require chemical and physical amelioration. It is an incontrovertible fact that soils derived from given kinds of rocks have usually distinct needs, whereas such treatment may be wholly neglected in the case of soils derived from rocks of a different character. For these and other obvious reasons the agronomist, in order to be well equipped to meet situations which may arise in another state, or in a new position to which he may be called, will find it of distinct aid if his fundamental educational equipment includes geology, mineralogy and physics in its special application to the many problems of the soil.

The agronomist will be brought face to face with emergencies and questions involving physical chemistry, the foundation for which is supplied not only by general chemistry, but also by knowledge of mathematics involving the calculus.

Finally, above and before all should be placed the subject of English, the call for which in some station bulletins is obvious, and in the use of which none can be too proficient.

It may be argued that the fundamental educational requirements as presented encroach upon other domains of science, that they are too comprehensive and are more exacting than the conditions demand. Nevertheless our progress as agronomists can not attain its maximum by depending wholly upon men who are trained only in a narrow specialty. Those engaged in given lines of agronomical research must have a sufficiently broad training in order to grasp the significance and bearing of factors lying frequently much outside of their strict domain. Had not Hellriegel

possessed an outlook broader than that circumscribed by the mere limits of chemistry, it is problematical if the discovery of nitrogen assimilation through the intervention of microorganisms might not have remained a problem for ourselves.

It is not enough that the teacher or investigator in agronomy be skilled in its art, but he must be trained in all of the natural sciences which are closely related to crops, fertilizers, soil amendments and to soils themselves in all of their several relations. The man who looks forward to service in the west or middle west can not neglect the chemistry of fertilizers in their relation to the special crop and to the special soil, for the fertilizer problem is advancing westward at a rapid rate and many of the present-day needs of the east will, in the near future, become the needs of much of the west and middle west.

From what has been said it must be obvious that the ordinary college course can not be considered an adequate preparation for the life work of the agronomist, whether he be engaged in teaching or in research, but that this must be supplemented by at least three years' work at the university. Conversely, it must be equally obvious that he who would succeed in the fullest degree in his scientific achievements in the domain of agronomy must also be familiar with the subject as an art, and if this knowledge was not acquired at home on the farm, before the beginning of the college course, it should surely be made a part of his equipment before entering upon the university course.

The demands of the times make imperative not only a knowledge of the art of agronomy and the possession of the foundation contributed by the college and university, but they demand that the teacher or investigator keep continually in touch with the work of others in this and other

countries, and to this end a reading knowledge of French and German, and if possible of other foreign languages, is essential. The argument that it is sufficient to merely read the abstracts of papers is specious. The investigator should never be content with anything short of the original, since ideas as to the relative importance of the different parts of an investigation are often widely variable, dependent upon the outlook or particular experience of the abstractor. It, therefore, not infrequently happens that a point which may be passed over as insignificant is vital to the work of some investigator, who, if confined solely to consulting the abstract, might never be able to profit by it.

It is obvious that the teacher must have sufficient time at command for daily recreation if he expects to maintain himself in condition to present his subject matter year after year to his classes in a clear and forceful manner. The same thing is necessary for the investigator in order that he may be keen and alert in the pursuit of his problems. He is then in condition to recognize points of attack which the man pressed and wearied with many duties might pass by unnoticed. To him who would be a strong, full man, capable of imparting inspiration to his students or of attacking problems of research with the true enthusiasm which is essential to success, time must not only be allowed for renewal of physical strength and for abundant reading, but *also for undisturbed and consecutive thought*. This means that no institution can long expect to be a leader in the field of education or in research, if its policy is to demand so much by way of other duties or so many hours of teaching that its employees can become leaders neither in thought nor in research in their chosen specialties. A university president, in a recent address, announced that those

teaching at his institution were hereafter to be measured for their fitness by their output in research. Such a policy, while prompted by a commendable spirit, might be more nearly applicable in a new institution in which the teaching demands are reasonable, but it is likely to work the grossest injustice if applied immediately in a college where worthy professors have grown old in a treadmill of exacting service, which has left no time for gathering inspiration nor for work of research. Such men, if given the opportunity at the right time, might have won a national or world-wide reputation as investigators, for they may have been original, diligent and fired with an enthusiasm which the institution itself gradually smothered and snuffed out. Such men should not be cast aside like an exhausted sponge, for the institution and the state owe them a debt which they can not repay. Again, a college professor can not always do his best work if made to feel that his tenure of office depends upon his yearly output in research. Such avowed watchfulness by a president or by a committee on efficiency is likely to lead to superficiality, to hasty publication, or to create unrest disastrous to research of a high order and to bring many disastrous consequences in its train.

Object lessons of spoiled investigators are especially common, in many of the smaller colleges, and even in many of the larger ones; yet the time may never come when it will be safe to measure the fitness of all men for college teaching solely, or even chiefly, by their research output. Nevertheless, one can not but recognize the desirability of encouraging teachers to practise exhaustive reading on special subjects, or to undertake special advanced research, whenever the demands of their positions and the attendant circumstances render it possible.

From what has been said it would appear that all teachers, and those who are selected to conduct research, should have at least three years of university training superimposed upon the college foundation. In saying this the writer recognizes that some of the best men in the country have not had this experience, but yet have won an enviable reputation in their respective lines, even in certain cases outstripping many who have enjoyed a more extensive fundamental training. It must, nevertheless, be recognized that such men have succeeded not in consequence of their handicap, but in spite of it! They were close observers, diligent students, and were possessed of original and judicial minds.

Admitting that the university training is a great desideratum in all cases, the problem presents itself of lending sufficient encouragement to young men so that they will be willing to devote three of the best years of their lives, and a large sum of money, to university study.

At almost every session of the Association of American Agricultural Colleges and Experiment Stations some college or university president or station director has bemoaned the difficulty of finding adequately trained men to fill the higher positions, especially in research. Indeed, the Secretary of Agriculture, the Hon. James Wilson, has repeatedly stated in public addresses that the Department of Agriculture finds it impossible to secure in this country men adequately qualified for many of the positions in the federal service, on which account his department is forced to train its own men. This leads to the query: Why does not the same principle of supply and demand hold as in lines of industry? It is a fact, which I think will be disputed by none who are well informed, that this country furnishes exceptional opportunities to-day for the young man just out of

college. Perhaps, indeed, if some of them, like men known to the writer, were forced to begin, after completing a four-year college course, at a salary of from \$16 to \$20 per month, all of which was required for board and clothes, they might be willing to make greater sacrifices than at present in order to insure for themselves a future, by securing a university training at whatever cost. To-day, however, the young graduate can readily command an initial salary of from \$800 to \$1,200, and many have been advanced within from two to three years to salaries as great as, or greater than, those paid in other reputable colleges to much older and more experienced men who have enjoyed a university training.

When these young men look about them in the institutions with which they are connected they may even find others at the heads of departments who have never enjoyed graduate study. They may also find those who have made the sacrifice, struggling by all sorts of means to add enough to their insufficient incomes to enable them to support a small family, with few comforts, no luxuries, and even with deprivation and need before them, in case of unusual illness or misfortune. It is no wonder, under such circumstances, that he thinks "a bird in the hand is worth two in the bush" and prefers to go on accumulating, rather than to spend three years' time and the savings of other years in order to secure the mere intellectual advantage of further study. As I have several times pointed out in public addresses, there can be no permanent remedy for such a condition short of an assured pension for those who have given ten to fifteen years of efficient, faithful service to such colleges and stations, or there must be occasional half-year intervals of freedom and a marked and progressive increase in compensation for the older and experi-

enced men. As concerns pensions, one that does not become assured until the end of a thirty-year period of service, while a great boon to those who finally receive it and a welcome aid to the president in unloading undesired or superannuated professors, nevertheless fails to furnish that assurance of security in case of disability or later financial difficulties which encourages the professor to satisfactorily equip his library, to travel, to study and to surround himself by the broadening influences which are essential to his greatest intellectual development and to his greatest usefulness to the students who come under his instruction. In this matter of pensions and conditions surrounding them we have a valuable lesson to learn from Germany.

It has been argued by some that the early assurance of a pension robs the prospective recipient of initiative and enthusiasm in his chosen profession and encourages a letting up of his intellectual activities. To such as advance this argument the writer begs to enter an emphatic denial of the justness of the accusation, for from his personal acquaintance with professors in many of the leading German universities and his observation of their spirit of research, he is convinced of the utter incorrectness of such a position. Indeed, nowhere in the world could one find greater devotion to duty, greater willingness to make personal sacrifices, or greater zeal in investigation, than among the professors of these German universities, who can look forward complacently to the future if disabled, and in any event with the comfort and knowledge that their families, after their work is done, will be cared for properly as a reward for a lifetime of faithful public service.

Finally, this society will do well to encourage the development in our universities of higher and broader graduate courses

in the applied sciences related to agriculture. Let us use our influence as a body to secure from the Carnegie Foundation, for the teacher and investigator in the smaller land-grant colleges, the same fair and just recognition for quality and amount of public service rendered as is accorded to the teacher of mathematics or of the classics in the older classical colleges of the country. If necessary, let the American Society of Agronomy urge upon congress the provision of a pension system for the land-grant college, based upon a reasonable probationary limit of service as a condition for its becoming assured. If to this these colleges will add the sabbatical year, or will allow a full half-year in every five, and will give adequate and progressive advances in salary with the years of service, we shall soon see plenty of young men fitting themselves well for the work of teaching and research.

In closing I would not fail to emphasize that young men entering our profession should do so with the missionary spirit and with the desire to serve their fellows uppermost in mind, but the situation to-day is such that many who set out with courage are forced, out of justice to their families and through failure to secure the reasonable comforts and necessities of life, to seek, against their will, such financial returns in other callings as are rarely the reward of the agricultural teacher and investigator.

H. J. WHEELER

*THE INTRODUCTION OF PHYSICAL CHEMICAL CONCEPTIONS IN THE EARLY STAGES OF THE TEACHING OF CHEMISTRY*¹

THE question I have been asked to discuss is not a new one, but is, in my opinion, one of fundamental importance. Whenever any

¹ Paper read before the American Chemical Society in Washington, December 27, 1911.

great advance has been made in any branch of science, the question has arisen how early should this be incorporated in the teaching of that science; in a word, how closely teaching should follow research, and various answers have been given.

That we are dealing here with a fundamental question is obvious after a moment's reflection. Shall we teach the beginner, in a judicious way, of course, the science as it is at the time in question, or shall we teach him what is not only hopelessly out of date, but what is known to be absolutely untrue?

In answering this question we must take into account that the beginner of to-day is the advanced student of to-morrow, and the chemist of the near future. It is true that most of the beginners in any branch of science never pursue that science at any length, and to these perhaps the least harm is done by teaching the science in an out of date manner; but the question becomes more serious when we are dealing with those who propose to devote their lives to the branch of science in question.

Why has the question that we are discussing arisen at this time? As is well known, it has come to the front as the result of certain fundamental discoveries made in chemistry towards the later part of the last century. These are usually known as *physical-chemical generalizations*, because they were reached through the application of physical methods to chemical problems.

I think the term "physical-chemical" is unfortunate, because it may leave the impression that we are dealing here with something different from chemical, while, in fact, we are not. Indeed, I think the term "physical chemistry" is unfortunate, since it may lead to the conclusion that here is something that is not chemistry, while it is simply an integral part of chemistry. I greatly prefer the term "general chemistry" or "generalized chemistry"; since the generalizations which have been reached in this field concern most vitally and fundamentally the whole science of chemistry. This same thought is echoed in the title of Ostwald's great work, "Lehr-

buch der allgemeinen Chemie." The term "physical chemistry" is, however, so widely disseminated, and the leading journals in this field in German and French both bear this title, so that the hope of reform in this nomenclature seems remote.

The generalizations that we have in mind are: The discovery of the Law of Mass Action, by the Norwegian physicist, Guldberg, and the Norwegian chemist, his son-in-law, Waage, in 1867; the discovery in 1886 of the applicability of the laws of gas-pressure to the osmotic pressure of dilute solutions of non-electrolytes, by one of the greatest men of science who has ever lived, Van't Hoff; and the explanation by Arrhenius in the same year, of the apparent discrepancies presented by electrolytes, *i. e.*, the announcement of the theory of electrolytic dissociation; of less importance perhaps is the interpretation of chemical valence in terms of Faraday's law, but scarcely so, at least from the pedagogical standpoint; and finally, the discovery of the electron, by Sir J. J. Thomson, and the instability of the chemical atom, by Rutherford.

The question then is, shall these generalizations be taken into account in the early stages of the teaching of chemistry, or shall they not? I know of no productive chemist who doubts the value of introducing them into more advanced stages of work. To do so would be to teach and learn a science of chemistry, with the science all left out.

A fair way to judge of the value of any discovery is to imagine that it had not been made, and see how the science would be affected by its absence. Similarly, in dealing with a question like the one under discussion, it would seem to me that a logical way to approach it would be to ask, What is lost by not incorporating the modern advances into elementary chemistry, and then what is gained by doing so?

It is certainly true that if we omit these generalizations from the early stages of chemical work we are teaching something that is out of date. There can be no two opinions on this point. But this alone does not solve our problem.

Perhaps the science as developed twenty-five years ago is better adapted to teaching the beginner than is the chemistry of to-day. It is certainly simpler. Why not teach the first year student in chemistry, in addition to a judicious number of the empirical facts of the science, something about the atom and the molecule, and leave it for a later stage to present the more recent developments? What would be lost by so doing? We have now arrived at a fundamental question.

The answer to this question is, in my opinion, that we must no longer teach the chemistry of three or four decades ago, because we know that in many fundamental points it is *untrue*. But it might be answered, we grant you this, but for the sake of *simplicity* we will teach the old chemistry, for, say a year, and then turn the student over to the new.

It is right here that an insuperable difficulty is encountered. It is the *persistence of first impressions*. Any one who has observed this at all carefully knows how nearly impossible it is to correct erroneous first impressions. Whatever the physiological or psychological explanation of the persistence of these impressions may be, the fact remains.

I have had this brought home to me so often and in such a forcible manner that it has made a deep and lasting impression. It has been my lot to try to teach something of the newer developments in chemistry to some students who have been trained in the older school. The result has been that it has required years of incessant drilling to ingraft the new generalizations into the mind of such a student. At first, the newer conceptions were scarcely more than tongue deep. In answer to questions it would be stated at first that "it is said" that such and such is true, or "the book says," or "you said" that this or that is the explanation; all of which went to show that the new ideas had penetrated hardly more than skin deep, and this, notwithstanding a serious effort on the part of an honest student to make the real science of chemistry an integral part of himself.

What is the explanation of this rather distressing condition of things? *Erroneous first*

impressions, from which it is almost impossible wholly to escape.

There is one other matter to which I should like to refer before leaving this part of the discussion. This is the tendency which has existed in the past in this country to make chemistry *easy*. I do not believe there can be much difference of opinion as to this being a fact. How often and how justly have we heard the elementary course in chemistry branded by the student body as a "snap"; and for this very reason a preponderating number of students elect this course.

This condition is nothing less than *fatal*, as far as the science of chemistry is concerned; and every serious teacher must study its cause and apply the remedy.

How has this condition come about? Largely, I believe, as follows: A quarter of a century ago chemistry was almost wholly an empirical branch of science. Rowland used to say that chemistry in his day was in the same stage of development as physics in the days of Michael Faraday; and this was only a slightly exaggerated statement. It was necessary at that time to present the subject of chemistry largely by the empirical method. The result was with chemistry, as with any other empirical branch of science, the comprehension of the subject involved primarily, and may I say chiefly, the memory. A reasonably developed memory is much more general than equally well developed reasoning powers, and the use of the latter involves the expenditure of far more mental energy than the use of the former. This is the reason why chemistry was regarded as *easy*. It was something that could be readily memorized.

While this was perhaps a more or less necessary condition, several decades ago, those conditions are now largely changed. Chemistry is rapidly advancing along the way to become a branch of exact science, and it can be dealt with to-day in no small measure by the deductive method.

Far be it from my purpose to make chemistry *hard*, or even harder than is necessary for the best good of the science, at least in the early stages of the study of the subject; but a

far more important object than to make chemistry easy is to make it scientific. The object of the teacher should be to make the subject *clear*, but I have not very much respect for making things easy, since in science whatever is *easy* is *superficial*. There is no inherent reason why we should make elementary chemistry appreciably easier for the average student than elementary physics; that is to say, make it more superficial.

The argument against introducing the newer generalizations into the elementary teaching of chemistry, based upon the fact that their omission renders the subject easier, is, then, in reality a strong argument in favor of incorporating them.

The question as to whether it is easier for the teacher to introduce or omit the newer conceptions does not enter into the present discussion, since every efficient teacher is abreast with the development of his science; and furthermore, in matters of teaching, it is only the best good of the student that is to be considered.

Let us now turn to the other question: What is *gained* by teaching elementary chemistry from the standpoint of the newer generalizations?

A beginner in chemistry soon learns that when a chloride is treated with concentrated sulphuric acid, hydrochloric acid gas escapes, and the chloride is transformed into the corresponding sulphate. At one time this was explained as due to the greater *strength* of sulphuric acid; but we can not offer this explanation any longer, since we now know that sulphuric acid is only a little more than half as strong as hydrochloric.

The same beginner quickly learns that when a solution of a chloride is treated with a solution of silver nitrate, insoluble silver chloride is precipitated.

These two classes of phenomena are typical of a large number of chemical reactions. In the past such facts were summarized by saying that whenever a gas can be formed it is formed, and whenever a solid can be formed it is formed. This was simply *renaming* the phenomena in question, but of course explained

nothing. Yet it was the best that could be done at that time.

It is a very simple matter to give any one, and therefore a beginner in chemistry, some qualitative conception of the effect of mass or quantity on chemical reactions—chemical reactions being dependent upon two things, the nature of the substances brought together, and their relative quantities. If the beginner can grasp one of these conceptions he can grasp the other.

Given the conception of mass and even qualitatively its function in chemistry, the two typical reactions mentioned above can be interpreted or, indeed, explained.

Hydrochloric acid having a low boiling point is a gas at ordinary temperatures, and escapes from the field of action almost as rapidly as it is formed; its active mass being thus reduced nearly to zero.

The silver chloride formed is nearly insoluble in water. It is precipitated as a solid and its active mass is thus small. I think this treatment renders the two typical reactions more clearly understood, and is more scientific than simply renaming the phenomena.

I venture to predict that not a few students of chemistry, not only of one year's standing but of several, are without any adequate conception of the importance of that condition in which matter in a given state of aggregation is, when mixed with matter in the same or a different state of aggregation—in a word, of the importance of *solution*.

If they were told that the whole science of chemistry is a branch of the science of solutions, they would either not understand the statement at all, or would regard it as a gross exaggeration.

It is a simple matter to make this reasonably clear, at least towards the end of the first year's work in chemistry. By that time enough reactions have been studied to show the student that practically all, if not all chemical reactions take place in solution, using the term solution in the broad sense in which it is employed to-day. Matter in the pure homogeneous condition is scarcely

capable of doing anything chemically, and that the science of solutions is much broader than chemistry will be seen after a moment's reflection. Geology is largely a science of solutions—of aqueous solutions and molten magmas, and how many branches of the biological sciences owe their existence to matter dissolved in other forms of matter?

In the pure homogeneous condition matter is, as we have stated, relatively inert. Nature, and, consequently, the science of nature, is, as it is, primarily due to matter in the dissolved state; and our knowledge of solutions, thanks to Van't Hoff and Arrhenius, is now reasonably satisfactory. We know far more about matter in the gaseous state than in the liquid or solid state. Van't Hoff has shown us that we can deal with solutions in many fundamental respects as we deal with gases. Consequently, we know far more about matter in solution than in the pure homogeneous liquid or solid condition. Why should these facts be concealed from the student of chemistry until late in life?

And now we come to another fundamental matter—the nature of the units that take part in chemical reaction. For a long time it was taught that the atoms and the molecules are the active chemical agents, and this was in keeping with what was known at the time.

This is now largely changed. The number of concordant lines of evidence which show that electrically charged parts are necessary for chemical activity, is so great, that I know of no productive chemist to-day who seriously questions it. After thinking over this problem and working upon it for a good many years, I am of the opinion that there is no chemical reaction known to man in which at least one of the substances taking part in the reaction is not more or less ionized. Indeed, I am unable to form any physical conception of even the possibility of a chemical reaction between electrically neutral parts, any more than I can form a conception of two electrically neutral bodies attracting or repelling one another electrically. It would lead us much too far to discuss at all fully this question here, nor is it necessary to do so.

To furnish evidence to-day for the general truth of the theory of electrolytic dissociation, would be as unwise and as useless as to furnish new evidence for the law of the conservation of energy, or for the law of the conservation of mass.

In the light of these facts are we justified in continuing to teach the beginner the old chemistry of atoms and molecules, which we know, or should know, is untrue; trusting to later years, to new experiences, or to another instructor to correct these erroneous first impressions, which, as has been stated, is well nigh impossible.

Take another phase of things. A phenomenon which must be encountered very early in the study of chemistry is *precipitation*, already referred to in another connection. Has it been possible to treat this subject scientifically until quite recently? I think not. Whenever a precipitate could be formed it was formed, was about the way this matter was left. In the chemical reaction in question a solid is formed, which is practically insoluble in the solvent used; and being insoluble it is thrown down in that coarse-grained condition that we call a precipitate.

Think of this for a moment. When the solid was formed it was probably in a state of molecular aggregation. How do these solid molecules know enough to come together and form aggregates of the sizes that exist in precipitates? Furthermore, if this is the "natural condition" of insoluble solids when formed in a chemical reaction, then why do we not *always* have precipitation when an insoluble solid is formed in a reaction? In a word, why do we have in some cases *colloidal suspensions*?

To fix the idea and by way of illustration, why is arsenic sulphide precipitated when arsenic chloride is treated with hydrogen sulphide, but is not precipitated when arsenic oxide of the same concentration as the chloride is treated with hydrogen sulphide? Not only must every teacher of chemistry have asked himself this question, but every intelligent student, before he has advanced very far, must do so.

This is now very satisfactorily explained by another really great man of science—a man whose work for chemistry is quite as fundamental as his work for physics—I refer, of course, to Sir J. J. Thomson.

He has shown that whether or not precipitates are formed is dependent upon the presence or absence of appreciable numbers of charged parts or ions. Arsenic sulphide is precipitated from the solution of the chloride because the hydrochloric acid set free by the action of the hydrogen sulphide is strongly ionized. On the other hand, arsenic sulphide is *not* precipitated from the solution of the oxide, because no strongly dissociated substance is formed as the result of the reaction, and neither arsenic oxide nor hydrogen sulphide is strongly dissociated.

But Thomson does not stop with showing that ions or charged parts are necessary for precipitation. It was shown by Burton, working in Thomson's laboratory, why, or at least how, this is the case. Space will not allow me to go into this in detail. Suffice it to say here that the colloiddally suspended particles are charged electrically, and for any given colloid all of the particles are charged with the same sign. These electrical repulsions work counter to surface-tension, which acts so as to draw the particles into the smallest surface for a given mass—to draw the colloiddally suspended particles into lumps as in an ordinary precipitate. When ions are present these electrically neutralize the charges upon the colloiddal particles and allow surface-tension to produce its full effect.

That ions are necessary and sufficient to effect precipitation, can readily be shown by adding almost any electrolyte to the colloiddally suspended particles of arsenic sulphide, obtained by treating the oxide with hydrogen sulphide. A precipitate is formed at once.

This work places the whole subject of precipitation, for the first time, upon a scientific basis, and while it can not be presented fully to a beginner, I see no reason why it should not be judiciously taught to a student in his second year of chemistry, *i. e.*, when he is

studying qualitative and quantitative analysis.

Then arise some of the most fundamental problems. What is a chemical atom? If made up of parts what are these parts, and how are they arranged within the atom? How does one chemical atom differ from another chemical atom? Are the chemical atoms stable?

These matters must all be taught the student of chemistry and the question is when? They can not of course all be presented fully to what we ordinarily mean by a beginner, but I can see no reason why they can not be presented, in an elementary manner of course, at the proper places, even in the first year's work in chemistry, unless we are wedded to the dogma that chemistry must be made *easy* in order that it may be *popular*.

We can certainly no longer teach that the chemical atom is an "ultimate unit" in the light of the recent work of Thomson. We know that it is made up of parts, and furthermore, we have some idea how these parts are arranged in two dimensions in space in a section through the atom. We have very good reason to believe that most, if not all of the differences between the atoms of the various chemical elements are a function of the number, arrangement, and possibly the velocities of the electrons composing the atoms. And why not, in a common-sense manner, tell the student of chemistry so, even in the comparatively early stages of his work?

Indeed, I think it is far simpler to teach this fundamental connection between the elements, than to have the beginner look upon the eighty or more elementary substances as so many discrete, disconnected, and fundamentally unrelated kinds of matter—to say nothing of it being true; and in the teaching of science I think *truth* is even more important than *simplicity*.

And again, take the question of the *stability* of the chemical atom. The stable atom of the past is now hardly more than historically interesting. The work of the Curies and especially of Rutherford, on radioactive sub-

stances, has placed this almost beyond the pale of doubt. The atoms with the largest atomic masses are certainly unstable, and it is highly probable that the atoms of all the elements are undergoing devolutionary changes.

In the light of these facts are we going to persist in teaching the stable atom, without qualification even to the beginner, and rely upon time, fate or the effort of some one else to correct, if possible, the evil that we have done? It is perfectly true that the stable atom is simpler for the beginner than the unstable atom, but here again it is *simplicity vs. truth*.

In conclusion, there is one other matter which I can not leave untouched, because it lies at the very foundation of our science. I submit that no serious student of chemistry, and this is the class for which we must be most concerned, can study the subject for six months, learning that certain things react chemically with certain other things, and that certain things do not react with one another, without asking himself the question, why is this? Why do some substances react, and why do others not react? If this question is not raised by the student it certainly should be by the instructor. The question then is, why do chemical reactions take place at all?

We might almost call this the most fundamental question of chemical science. It is certainly so for the student, and that in the early part of his career. This brings me to the most heterodox position that I have yet ventured to take.

Should we not introduce into our elementary courses in chemistry something about the *energy changes* that take place in all chemical reactions, and which make those reactions possible? In the evolution of chemistry the material changes were studied first, and this was natural. These changes were the most obvious, and the material products were often desired for one purpose or another. Again, these material changes were the easiest to study, and chemists, like other men, were inclined to follow the lines of least resistance. I believe the nineteenth century will go down

in the history of chemistry primarily as the period of *material chemistry*.

But even this is changed now. Without decrying in the least the study of matter, the chemist of to-day insists that we can no longer ignore the changes in energy that manifest themselves in every chemical reaction. Indeed, he would even go further, and point out again that whatever is easiest in science is relatively most superficial.

We know to-day that *all* chemical reactions are really due to differences in the intensity, or quantity, or kind of the intrinsic energy present in the substances that are to react; and whether any two substances will or will not react is determined primarily by this difference. We can, furthermore, form a physical conception now of what is meant by intrinsic energy, since we have the electron theory of the atom; it is primarily the kinetic energy of the moving electrons within the atom.

But dare we venture even to refer to energy or energy changes in the early stages of the teaching of chemistry? I ask why not? The physicist does not hesitate to do so. Indeed, most of his subject has to deal very largely with changes in the different manifestations of energy. Why should we assume that the chemical student has less natural intelligence than the student of physics, especially when he is almost always the same student? (In my opinion no one should be allowed to begin the study of chemistry until he has had at least one year of physics.

There is, of course, no reason for assuming that the beginning chemist is not as intelligent as the beginning physicist, and, therefore, there is no more reason why a student of chemistry should not deal with changes in energy than a student in physics, especially when these energy changes are as fundamental for chemical science as they are for physics.

Instead of teaching to-day that chemical reactions are *accompanied* by energy changes, why not teach the truth, which is, that it is these very energy changes that are the cause of all chemical reaction? Systems which alone are fairly stable, when brought together

may become unstable. There is a running down of a part of the intrinsic energy of one or both of the substances into heat, light or electricity but almost always largely into heat; and the substances rearrange themselves into those new combinations which are most stable under the new conditions.

This is what we ordinarily describe as a chemical reaction, and this can be taught to any sensible student just as well as the elements of physics can be taught to him.

Finally, the matters herein referred to, together with many others which time will not permit me even to mention, can not, of course, be taught the beginner all at once, in addition to the so-called material facts of chemistry. It is, however, a fair question to ask whether some of these matters would not be a fair substitute for a part of the pyrotechnics that sometimes adorns the chemical lecture table?

In all such matters the judgment and common sense of the teacher must of course be the final guide, and the intellectual fiber of the student must also be taken into account. It goes without saying that we must not teach dogmatically anything to the student of chemistry, much less to the beginner in chemistry, that is not reasonably substantiated; but I believe that all of the matters referred to above and many more of their type belong in this class.

The final question then is, shall we have two chemistries or one? Shall we have a chemistry of research, pushing forward at a pace that makes the last twenty-five years mark a distinctly new epoch in the history of the science? and another chemistry taught the beginner, which practically ignores all that has been done within that period; which deals not only with what is obsolete, but with what we know to be largely untrue, and which relies upon subsequent teaching to do almost the impossible, *i. e.*, correct erroneous first impressions, which must in some method be corrected, or the result is fatal?

Or shall we have one science of chemistry? Research leading the way, and teaching following fairly closely behind? At least doing

nothing that will have to be undone, but incorporating what is truest and best.

For those who believe as I do that the latter is the more scientific course, there is not only no ground for pessimism, but not even for pragmatic meliorism.

The progress in this direction during the last decade, not only in the better colleges and universities, but in the more progressive high schools, has been so rapid that there is room for nothing but the most cheerful optimism.

HARRY C. JONES

IS SCIENCE REALLY UNPOPULAR IN HIGH SCHOOLS?

THE period covered by the tenth decade of the nineteenth century and the first of the twentieth was one of great activity in the reconstruction of high school schedules. The reports of the N. E. A., Committees of Ten and on college entrance examinations, the formation of the College Entrance Examination Board, the Perry and other movements for the reform and unification of science and mathematical teaching, all must have influenced high school curricula, and the alterations of the curricula must have shown effects in the percentages of secondary students in the various courses.

The famous attack made by President G. Stanley Hall¹ on the methods and attitude of secondary teaching in the United States was based to a certain extent on the summary tables of the percentage of secondary students in the United States taking the various high school studies, and published in the reports of the Commissioner of Education, 1890 to 1907. In order to exhibit these I have plotted the data on a chart. The curves for studies, graduates and college preparatory students are from the summary table (p. 1052), Report of the Commissioner of Education for 1907; that for per cent. of secondary students

¹G. Stanley Hall, "How Far is the Present High School and Early College Training adapted to the Needs and Nature of Adolescents?" N. E. Asso. Coll. and Prep. Schs., 16, p. 72, 1901; *Ped. Sem.*, 9, p. 92, 1902; *Sch. Rev.*, 9, p. 649, 1901.

in the total population, from table on p. 1044. No curves are plotted for trigonometry and psychology, as they have never been of appreciable importance as high-school studies; the curves for Greek and geology are omitted, as they so nearly coincide with that for astronomy as to cause confusion.

Certain facts stand out from the curve-sheet. Greek has declined; so has civics; Latin, modern languages, English literature, rhetoric and foreign history have all increased, some of them enormously; *all the natural sciences* have fallen—geology, astronomy, chemistry, physics, physical geography and physiology have all dropped down, some of them enormously. Meanwhile the percentage of graduates has increased—a good showing, indicating that students are better satisfied with the schools than they were formerly—the proportion of students preparing for college has diminished, and the proportion of secondary students to total population has nearly doubled.

It is well known that the proportion of secondary students in the earlier years of the course is greater than that later. Hence a possible cause of an observed diminution in popularity of a subject is the alteration of schedules so as to shift the study into the later years of the course, and *vice versa* for an increase of popularity. Then the remarkable growth of the elective system, which occurred largely in the period covered by these curves, and the actual withdrawal of courses, are other causes which would affect the percentages. Now if we can in any way numerically express the opportunity which the average student has to take a given study, and compare with this the amount to which he takes advantage of his opportunity, as expressed in the tables of the bureau, we have in the ratio a numerical measure of the popularity of the study. I hope to be able to do this in a rough way from data already published, and to show that the drift away from science is in part at least the result of schedule tinkering, and does not completely express the taste of that much-criticized phenomenon, the rising generation.

If we can find the probability that a student selected at random from the mass shall be in any particular year of the high school course, and also the probability that a particular subject shall be offered by his school in that year, then the probability that this randomly selected student shall be taking this subject in this year is the product of these two probabilities, on the supposition that the subject is *required of all students* in this year. And this probability is also the percentage of students in the great mass who would be taking this subject in this year under the same supposition of no election.

The first probability is given by the Commissioner of Education in the Report for 1907, p. 1046, where it is said:

For several years this bureau has estimated the proportion of secondary students in each of the four years as 43 per cent. in the first year, 26 per cent. in the second year, 18 per cent. in the third year and 13 per cent. in the fourth year. This estimate was based upon the enrollment of secondary students by grades in the high schools of a number of cities.

Two things show that this is not a constant distribution. First, the bureau has for three or four recent years collected data of this sort for the whole country, beginning with this report of 1907, and the figures do vary a fraction of a per cent. from these estimates. Second, the percentages for high-school graduates charted on the curve-sheet, show that the proportion of graduates in the high-school population has gradually increased, being 10.05 per cent. in 1889-90 and 11.87 per cent. in 1905-6. But in spite of this evident, though not very large, variation, we have no other means of getting at the facts, and will use these mean values as representing the probability of a randomly selected student's being in any particular year of the course.

The means for estimating the amount and effect of schedule tinkering is very incomplete. An article by Professor E. G. Dexter¹

¹ E. G. Dexter, *Sch. Rev.*, 14, p. 254, 1906; "Ten Years' Influence of the Report of the Committee of Ten."

gives the only statistics available for this purpose, so far as I know. He collected the printed programs of schools for the period just preceding 1894, when the report of the Committee of Ten would not yet be effective, and for that ten years later, and compared the two. In his own words:

For the earlier portion of the study 80 schools were covered: 35 in the eastern section of the country, 25 in the middle west and 10 each in the south and far west. For the period a decade later the number of schools was 160: 49 being in the east, 46 in the middle west, 30 in the south and 35 in the far west.

Neither these numbers nor the particular schools studied were the result of arbitrary choice, but in most cases of dire necessity. Every available course of study for the years 1892 to 1894 was considered, and this was essentially true for the period ten years later. So far as possible, the same schools were considered at both periods; but, as indicated by the figures, many more schools were included in the later than in the earlier study. This was that errors due to accidental conditions might be reduced to a minimum. I have not thought it necessary in this paper to give the names of the particular schools studied, but will say that the list includes the high schools of nearly all the larger cities of the country; and that none of the smallest schools are covered is suggested by the fact that only those issuing printed courses of study are included. The part of the study covered by this paper has to do only with those recommendations of the special subcommittees (of the Committee of Ten) which bear upon the high-school curriculum.

The second factor, the probability that the student will have the opportunity to take a study in the year in which he happens to be, can in most cases be computed from Dexter's data, in an approximate sort of way. I will give the computation for German in some detail, as in it appear all the irregularities which show themselves in connection with other subjects, and further, the resulting table contains the only essential absurdity which developed in the preliminary computations.

First, Dexter's table for German.

TABLE I

	1894	1904
Percentage of schools offering 2 years	34	25
Percentage of schools offering 3 years	33	36
Percentage of schools offering 4 years	33	23
Percentage beginning in the first high-school year or earlier	48	47
Percentage beginning in the second high-school year	30	41
Percentage beginning in the third high-school year	22	12

(I infer that 16 per cent. gave a 1-year course in 1904, beginning in year III.)

This table I rearrange and extend as follows:

TABLE II

1894				1904			
Begin	Per Cent.	Length	Per Cent.	Begin	Per Cent.	Length	Per Cent.
I.	48	{ 33 15 18	{ 4 3 3	I.	47	{ 23 24 12	{ 4 3 36
II.	30	{ 12 22	{ 2 3	II.	41	{ 29 -4	{ 2 25
III.	22	{ 0	{ 1	III.	12	{ 16	{ 1
IV.	0		{ 0	IV.	0		{ 16

The percentages opposite the half-braces ({} mean thus: For 1904 23 per cent. of the schools gave a 4-year course, while 47 per cent. began in year I.; hence 24 per cent. must begin a 3-year course in year I. Thirty-six per cent. gave a 3-year course, hence 12 per cent. begin the 3-year course in year II., etc. That this course of reasoning is imperfect appears from the fact that according to it —4 per cent. begin a 2-year course in year III., which is absurd. However, the difficulty lies in the original data being out of reach, and as the absurdity is not going to be of great influence on the computations, as it comes in the third and fourth years, I use the figures as they stand. The table for German is the only one in which any patent absurdity shows itself.

From this table I obtain the percentages which express the random student's opportunity to take German, i. e., the per cent. of students who would be taking German were it required wherever and whenever it is offered, thus:

The probability that a student be in the first year of the course is 0.43, from the data of the Bureau of Education; the probability that German will be offered in that year is (1904) 0.23 for a 4-year course and 0.24 for a 3-year course, or 0.47 for both; the desired probability is then $0.43 \times 0.47 = 0.202$.^{*} The probability that a student be in the second year is 0.26; the probability that German will be offered in that year is 0.29 for a 2-year course begun that year, 0.24 for a 3-year course begun in first year, 0.23 for a 4-year course, 0.12 for a 3-year course begun in second year. The resulting probability that a student be taking German, if it were a required study in second year, is $0.26 (0.29 + 0.24 + 0.23 + 0.12) = 0.232$. Similarly for the other years. Then the total probability that a random student be taking German in 1904 is 0.654. Computations like this carried out for the studies in Dexter's tables result in the following table.

TABLE III^{*}

Study	Per Cent.—if Required			Per Cent.—Actual			Actual	
							Required	
	1894	1904	Ratio	1894	1904	Ratio	1894	1904
Latin.....	69.2	91.4	1.32	43.59	49.96	1.23	0.63	0.55
French.....	64.8	66.0	1.02	10.31	11.15	1.08	0.16	0.17
German.....	72.0	65.4	0.91	12.78	18.98	1.49	0.18	0.29
Algebra.....	47.7	53.1	1.11	52.71	56.23	1.07	1.10	1.06
Geometry, plane.....	24.2	30.4	1.26					
“ solid.....	8.0	10.5	1.31					
“ both.....	32.2	40.9	1.27	25.25	27.30	1.08	0.78	0.67
Physics.....	21.3	22.0	1.03	24.02	15.90	0.66	1.13	0.72
Chemistry.....	11.5	10.2	0.89	10.31	7.08	0.69	0.90	0.69
Geology.....	11.0	5.6	0.51	5.52 ^b	2.79	0.51	0.50	0.50
Physical geography and physiography.....	29.8	27.0	0.91	22.44 ^b	21.26	0.95	0.75	0.79

^{*} In this it is assumed that all schools dealt with are of the same size, which is inaccurate, but unavoidable.

^{*} Results computed from the articles of Hunter, Weckel, Ramsay and Whitney, published in *School Science and Mathematics* during the last two years, supplement the above table in part. But they depend on limited or fragmentary data. A complete census by the Bureau of Education would be of great value.

^b 1894-5 data.

With regard to some of the other subjects tabulated by the Bureau of Education, I am not able to draw any conclusions from Dexter's tables and other data. Some of his facts may be quoted as supplementing the table above.

This goes far to explain the increase in the percentage of students studying foreign history, as tabulated in the commissioned report and shown on the curve-sheet.

Table III., in spite of the very inadequate data on which it is in part based, is capable of giving us a certain amount of information about the relations between election and schedule alteration and the data of the Bureau of Education. The columns headed “per cent.—if required” give in per cents. the probabilities for each study that a random student would be taking the subject if there were no elective system, as derived from Dexter's data, and hence also the percentages of students in the mass who would take the sub-

ject under these conditions. In a way they measure the average opportunity for a student to take the subject. The column “ratio” gives the quotient of the per cent. for 1904 by that for 1894. It measures the extent of schedule change. The columns headed “per cent.—actual” are quoted from the commissioner's table. The “ratio” column is found in the same way. The columns headed “actual/required” check the accuracy

of the methods used, and show that in three places there are errors; for it is manifestly impossible that in 1894 or 1904 there could be more students taking algebra or physics than would take it were the subjects required. Besides, these columns tend in the clearest way to show the effect of the elective system; the ratios measure in a rough way the popularity of a study, when it is elective.

TABLE IV

Study	Per Cent. Schools Offering	
	1901	1904
Latin, four years	46	80
Physics	97	100
Chemistry, mostly in year III.	74	66
Astronomy	63	31
Physiology, mostly in years I. or II.	81	57
Trigonometry	23	44
English,* four years	52	68
English, less than four years, more than three years	12	32

For example: in spite of the great increase in the percentage of students taking Latin, the subject had in fact declined in popularity, as shown by the ratios, 1894, 0.63, 1904, 0.55; further, these ratios show that, after all, relatively few students took the subject in comparison with the opportunities.

TABLE V
The History Branches

	1894		1904	
	Per Cent. Offering	Length of Year	Per Cent. Offering	Length of Year
American	57	0.7	86	0.64
French	0	0.0	7	0.50
English	39	0.5	51	0.66
"Intensive"	0	0.0	5	1.00
Greek	47	0.5	57	0.50
Roman	50	0.5	57	0.50
General	46	1.0	61	1.00

Examining the table with this in view, we see that French has hardly changed, while German draws increasingly on the affections

*The separation into English literature and rhetoric or composition is not sharp, and is hard to tabulate.

of secondary students—may this be a reflex of the great influence of German thought in the universities, brought into the secondary schools by college-bred teachers? But both French and German have a low popularity, lower than any science. Algebra is the universal study, not generally elective, and so it is not surprising that its "popularity" should be represented by a number in the neighborhood of 1. The excess gives a rough idea of the errors inherent in my data, and the amount of guessing which has crept in. Geometry was in 1904 not so generally required as in 1894, and so shows a fall of popularity. Physics was in 1894 more generally required than in 1904, which accounts in part for the drop from about 1.00 to 0.72. The balance means real dislike for the subject. Geology and physical geography and physiography stay about where they were in popularity.

I am inclined to conclude from this table that, in spite of a general impression to the contrary, American boys and girls like the sciences, both exact and natural, better than they like the languages, *provided they only have as good a chance to get at them*; and the way to save the situation for science is to give them the chance early in the course. I assert with confidence that, had 80 per cent. of Dexter's schools in 1904 offered four years of chemistry and physics, instead of four years of Latin, as they did, we should have found the figures of percentages just about reversed, or even worse for Latin.

WILLARD J. FISHER

ITHACA, N. Y.,
December, 1911

THE SMITHSONIAN BIOLOGICAL SURVEY
OF THE PANAMA CANAL ZONE

THE Biological Survey of the Panama Canal Zone, begun in December, 1910, and continued through the major part of 1911, is being pushed to completion before the opening of the canal in 1913. The second expedition sailed on January 9, to take up the work for another season, the botanist, Professor

Pittier, being the only naturalist who has remained in the field since the beginning of the survey. Although much interesting information has been collected, and a great many specimens secured, nothing like a complete report is ready.

The party will include Dr. Seth E. Meek, formerly of the Bureau of Fisheries, but now representing the Field Museum of Natural History; Mr. S. F. Hildebrand, of the Bureau of Fisheries, who will collect fishes, reptiles and amphibians; E. A. Goldman, of the Biological Survey, Department of Agriculture, who will collect birds and mammals, and Professor Charles D. Marsh, of the Bureau of Plant Industry, Department of Agriculture, who will collect and study the microscopic plant and animal life of the fresh waters of the zone.

Leaving New York on the steamship *Panama*, they will proceed to Cristobal, Canal Zone, their headquarters on the Atlantic coast, and there make preparations for a sojourn of four or five months in the field.

The life-areas on the zone will become confused as soon as the canal is opened and the waters of the Pacific and Atlantic watersheds are intermingled. It is particularly important on that account, that the present geographical distribution of animals and plants be recorded prior to that time, and this is especially true as regards the life of the fresh waters and the sea-coasts.

The work of the survey is carried on through the united efforts of the Smithsonian Institution, several of the government departments and the Field Museum of Natural History of Chicago, and the hearty cooperation of the Panama Canal Commission has been an important factor in the success of the undertaking.

As a preliminary of the work already accomplished, the Smithsonian has published four pamphlets. The first two (Nos. 2015 and 2053 of the Smithsonian Misc. Colls.) are by E. W. Nelson, of the Biological Survey, and describe a new humming-bird, a motmot and a bird of the genus *Pachysylvia*. The third, by E. A. Goldman, one of the naturalists of

the survey, contains a description of a new kingfisher.

Mr. Maxon, of the Division of Plants, National Museum, who accompanied Professor Henry Pittier to the Canal Zone last year, has published a description of a remarkable new fern (Smiths. Misc. Coll. No. 2055).

After all the new forms of animals and plants have been described it is proposed to publish general accounts of all the various collections and also one or more volumes containing a summary of the whole fauna and flora of the Canal Zone.

SCIENTIFIC NOTES AND NEWS

DR. J. A. ALLEN, curator of mammalogy and ornithology in the American Museum of Natural History, has resigned the editorship of *The Auk*, and the council of the American Ornithologists' Union, at the recent meeting in Philadelphia, chose Mr. Witmer Stone as his successor. Simultaneous with Dr. Allen's retirement Mr. Frank M. Chapman resigned as associate editor. Beginning in 1876 with the initial volume of the *Bulletin* of the Nuttall Ornithological Club, Dr. Allen guided the course of this journal and its successor *The Auk* since its establishment in 1884.

DR. J. WALTER FEWKES, of the Bureau of American Ethnology, has been reelected president of the American Anthropological Association. The next annual meeting of the association will be in Cleveland, Ohio, beginning on December 30, 1912, in affiliation with Section H of the American Association for the Advancement of Science.

DR. THEOBALD SMITH, professor of comparative pathology at Harvard and exchange professor at the University of Berlin during the present academic year, delivered his first lecture on January 8. His subject was "The Relation between Parasitism and Disease."

PROFESSOR GEORGE GRANT MACCURDY will be the delegate from Yale University to the eighteenth International Congress of Americanists to be held in London from May 27 to June 1, 1912.

MR. ALEX. WETMORE, of the Biological Survey, U. S. Department of Agriculture, is in Porto Rico this winter, cooperating with the Insular Board of Agriculture in studying the economic relations of the birds and mammals of the island.

PROFESSOR A. S. HITCHCOCK, systematic agrostologist, U. S. Department of Agriculture, has returned from Panama. About two months were spent in the Canal Zone and other parts of Panama, where he was a member of the Smithsonian Biological Survey, and about two months in the five Central American Republics. Nearly 200 species of grasses, represented by 565 numbers, were obtained in Panama and 760 numbers of grasses in Central America. While in Panama a trip was made to the extinct volcano Chiriqui, which has an altitude of a little over 11,000 feet. Besides several novelties there were collected many species heretofore known only from South America. Mr. Hitchcock was accompanied by his son, Frank H. Hitchcock, with whose aid he was able to obtain many duplicates.

WE learn from *The Auk* that Mr. Samuel N. Rhoads has returned from Ecuador after collecting at various points along the railroad which runs from Guayaquil to Quito, especially at Bucay (975 feet), on the Chanchan River (2,000 feet), Huigra (4,000 feet), Mt. Pichincha (8,000 feet), Riobamba (10,000 feet) and in the vicinity of Quito. He brought back about 1,600 birds, some mammals and reptiles and a number of invertebrates. His collection is now at the Academy of Natural Sciences, Philadelphia.

PROFESSOR L. H. HERTZ, of the University of Chicago, will give six lectures on the Herter foundation of the University and Bellevue Hospital Medical College, beginning on January 8. The subject of the lectures was "Immunity."

DR. WILLIAM H. WELCH, professor of pathology at the Johns Hopkins University, will give the lectures on the Barbour-Page foundation at the University of Virginia.

MR. GANO DUNN, president of the American Institute of Electrical Engineers, was the guest of honor at the annual dinner of the Ithaca Section of the institute, held on January 10. His subject was "The Kind of a Man that makes a Good Engineer."

MR. C. A. SELEY, mechanical engineer of the Rock Island Lines, delivered an address before the students and faculty of the College of Engineering of the University of Illinois, on January 4, 1912, on "Conference Committee Methods in handling Railway Legislation on Mechanical Matters."

BEFORE the Geographic Society of Chicago on January 12 a lecture was given by Professor R. H. Whitbeck, of the University of Wisconsin, the title of the lecture being "Geographical Names and the Stories they Tell."

AT the dedication of the Gauss monument on the Hohenhausen, near Dransfeld, the memorial address was delivered by Professor W. Voigt, of the University of Göttingen.

THE daily papers announce that Dr. Simon, the bacteriologist of Zurich, has died as the result of a bite from an inoculated mouse.

THE death is also announced of Dr. Stephan Lindeck, member of the Charlottenburg Reichsanstalt.

THE Society of American Bacteriologists, at its recent meeting in Washington, elected the following officers:

President—Dr. William H. Park, director of the Research Laboratories, City of New York.

Vice-president—Professor C. E. A. Winslow, College of the City of New York.

Secretary-treasurer—Dr. Charles E. Marshall, Michigan Agricultural College, East Lansing.

Council—Dr. W. J. MacNeal, New York Post-Graduate Schools, New York City; Dr. Otto Rahn, Michigan Agricultural College, East Lansing; Dr. H. D. Pease, 39 West 38th Street, New York City; Dr. John F. Anderson, director of Hygienic Laboratory, Washington.

Delegate to the A. A. A. S.—Professor D. H. Bergey, University of Pennsylvania.

DR. G. STANLEY HALL, president of Clark University, is giving a course of six lectures on "The Founders of Modern Psychology"

before the department of psychology of Columbia University. The lectures are on January 16, 17, 23, 24, 30 and 31, at 4.10 p.m. The subjects are as follows:

Edward D. Zeller, *the scholar in his field*. The historian of ancient philosophy, his personality, his learning, his career, characteristics as a teacher, his essays, historical method and position, and an estimate of his achievements.

Edward von Hartmann, *the philosopher of temperament*. Personal reminiscences of his traits, his early writings, outline of his chief positions in his major and his minor contributions, critique of his type of pessimism.

Hermann Lotze, *the harmonizer*. The man and professor, his early work as physiologist and physician, the chief position taken in his Microcosm and his Ethics, his system as an expression of his character and its historical significance. Why he never left a school.

Theodor Fechner, *the animist*. His life, works, personal reminiscences, his mystic papers, his unique type of idealism, his lapse to spiritualism, the psychophysics law and what it meant to him.

Hermann von Helmholtz, *the ideal man of science*. His boyhood, growth and early manhood, his methods of life and work, his essays and addresses, the fourth dimension of space, characterization of the chief discoveries in his optics and acoustics and their results.

Wilhelm Wundt, *a scientific philosopher*. His early career, his methods of work, his early, and a glimpse at his later, writings, some criticisms and appreciations.

Nature states that the jubilee annual meeting of the Yorkshire Naturalists' Union was held at Heckmondwike, on December 16, at the place where fifty years ago the union had its birth. There were more than three hundred members present, including delegates from thirty-eight affiliated societies of the Yorkshire Naturalists' Union. The presidential address of Mr. Alfred Harker, F.R.S., on "Petrology in Yorkshire," was delivered. Mr. T. Sheppard resigned his position as honorary secretary, and in view of his nine years' work in that position was elected an honorary life member of the union. Mr. W. Cash was similarly honored. Mr. J. W. Taylor, of Leeds, was elected president for 1912. The new sec-

retaries are Dr. T. W. Woodhead and Mr. W. E. L. Wattam, Technical College, Huddersfield. The annual meeting for 1912 will be held at Hull on December 14.

As we learn from the New York *Evening Post* an old landmark which has figured extensively in the medical and surgical progress of the city for nearly a half century is to be sold by auction on February 1. The property is the old Mott Memorial at No. 64 Madison Avenue, opposite Madison Square Garden. The memorial was founded in 1866 by the widow of Dr. Alexander Mott, who in his day was one of the foremost surgeons of this country. Many surgical and obstetrical instruments, invented by Dr. Mott, as well as numerous morbid specimens he collected during his travels, were partly destroyed with the burning of the Medical College on Fourteenth Street. His widow succeeded in gathering mementos of his life and placed them in the Madison Avenue house, which was incorporated as the Mott Memorial in 1866, and conducted for many years by Professor Alexander B. Mott. It contained a library of more than 4,000 volumes, exclusively on medical and surgical topics, which were consulted freely by students and physicians. In the will of Mrs. Mott there was a proviso that in the event that the property should become burdensome the trustees were directed to sell it. The Memorial, after several years of uncertainty, during which the trustees hoped a way could be devised to perpetuate it, was closed in 1909, and the books, instruments and plates were transferred to the New York Academy of Medicine, of which Dr. Mott was president for a long period.

THE fourteenth International Congress of Anthropology and Prehistoric Archeology, will be held at Geneva, Switzerland, during the first week of September, 1912. The last session of this congress was held at Monaco in the spring of 1906.

THE *American Museum Journal* reports that Mr. Stefánsson, of the Museum's Arctic expedition, has made a discovery of an archeological nature at his last winter camp near

Pt. Stevens, Parry Peninsula. According to his report a great deal of pottery is found upon old village sites, some at a depth of several feet. This pottery is of similar type to that found among and lately manufactured by some of the Alaskan Eskimos. Pottery has so far not been reported from any of the central and eastern Eskimos. It was formerly assumed that the presence of pottery among the Alaskan Eskimos was to be explained as indicating forms copied from Siberian or neighboring American tribes. The recent discoveries of Mr. Stefánsson indicate that the art of pottery among the Eskimos must have been of ancient origin and at one time very widely distributed. Furthermore Mr. Stefánsson reports that other objects he finds are similar in type to those described by Professor Boas, discovered by Captain George Comer in ancient village sites in Southampton Island, Hudson Bay. These were also similar to objects recently discovered in Greenland, leading to the conclusion that older types of Eskimo culture must have been much more uniform throughout the entire stretch of Arctic America than at present. Mr. Stefánsson's find of similar objects on the west side of Hudson Bay make more probable that there was formerly but a single type of Eskimo culture from Alaska to Greenland.

To demonstrate the process involved in changing raw materials into finished products, the course in commerce at the University of Wisconsin maintains a commercial museum for the use of the students in the course. Detailed exhibits of almost every product that has any commercial value are included. Among the most instructive are those of cotton, wool, silk, the grains and their products, rubber, steel and aluminum products and structural fibers. Different forms of money used in all parts of the world, and a collection of coins representing the circulating media of some of the less civilized peoples, are interesting features of this museum.

SURJOINED are the names of the members of the commission on resuscitation from shock, selected by the American Medical Association at the request of the National Electric Light

Association. This is the result of a series of conferences on the subject held during the past year by representatives of the leading engineering societies, officials of the government, etc. *Resuscitation Commission:* Dr. W. B. Cannon (*chairman*), department of physiology, Harvard Medical School. *Nominated by the American Medical Association:* Dr. Yandell Henderson, department of physiology, Yale University; Dr. Geo. W. Crile, 214 Osborn Building, Cleveland, Ohio; Dr. S. J. Meltzer, Rockefeller Institute. *Nominated by the National Electric Light Association:* Dr. Edward A. Spitzka, professor of anatomy, Jefferson Medical College; Mr. W. C. L. Eglin, Philadelphia Electric Company. *Nominated by the American Institute of Electrical Engineers:* Professor Elihu Thomson, ex-president of the American Institute of Electrical Engineers, Lynn, Mass.; Dr. Arthur E. Kennelly, Harvard University; Mr. W. D. Weaver (*secretary*), editor *Electrical World*, New York City. A conference was held on December 16 by the president and secretary of the commission and some preliminary work was mapped out. These steps will be followed up by an early meeting of the full commission, probably in New York in January, after which the plans adopted for the investigation will be vigorously pushed. It is felt that the much-needed revision of rules and practise in regard to this highly important subject will now be taken up under the best auspices and that authoritative conclusions will be reached. The officers of the association are highly encouraged in knowing that the question will receive the serious attention of these eminent medical men and that they regard it as worthy of their special study.

UNIVERSITY AND EDUCATIONAL NEWS

DR. JOHN GRIER HIBBEN, Stuart professor of logic, has been elected president of Princeton University.

DR. and MRS. CHARLES WALDSTEIN, of Cambridge, England, have given \$5,000 to Columbia University to establish lectures on the foreign policy of the United States.

THE trustees of Northwestern University have announced a gift of \$8,000 from the estate of Mrs. Ellen Sage which is administered by Mr. N. M. Jones, for the establishment of three scholarships: one in the College of Liberal Arts, one in the Medical School and one in the Law School, to be known as the Rufus H. Sage scholarships.

THE degree of bachelor of business administration will hereafter be conferred on graduates of Northwestern University School of Commerce who have had two years' regular college work and have spent two years in the School of Commerce.

BEGINNING with September, 1914, the Schools of Mines, Engineering and Chemistry of Columbia University, which comprise the faculty of applied science, will be substantially graduate schools, a baccalaureate degree being required for admission. But students will have the privilege of following a combined collegiate and professional course in engineering as they now have in law, medicine and teaching. The strictly technical or professional course of study will be three years in length instead of four as at present.

THE trustees of Teachers College, Columbia University, have created a School of Practical Arts, to comprise the present Schools of Household and Industrial Arts and the departments of fine arts, music and physical education. To this end there has been constituted a faculty of education, comprising the dean and the professors whose work is largely in education, who are to direct the School of Education, and the faculty of practical arts, including the professors of fine arts, music, household arts, industrial arts and hygiene and physical training. To this latter faculty is entrusted the development of the new School of Practical Arts, which is to offer a new type of university education—a four-year course, comprising both academic and vocational courses.

THE technique of printing and publishing is the subject of a new course to be given in connection with the work in journalism at the University of Wisconsin, beginning in Feb-

ruary. The course will consist of practical talks and laboratory work on typographical composition, engraving processes, printing and similar topics. The study is intended primarily for students of engineering, agriculture, commerce, pharmacy, chemistry and other technical subjects, who desire to familiarize themselves with methods of printing and publishing in order to contribute to or do editorial work on scientific, technical and trade publications. A course in technical and trade journalism, to include lectures and practise in all the details of the work of the editor and the contributor on scientific, technical and trade publications, has also been arranged to be given next year.

HERBERT SHAW PHILBRICK, assistant professor of mechanical engineering at the University of Missouri, has been appointed professor of that subject in the College of Engineering of Northwestern University.

DR. H. E. BUCHANAN has been appointed professor of mathematics at the University of Tennessee.

PROFESSOR GEORG FABER, of the Technical School at Stuttgart, has been called to a chair of mathematics at Königsberg.

DISCUSSION AND CORRESPONDENCE

THE ADMINISTRATION OF THE WEEKS ACT

TO THE EDITOR OF SCIENCE: In consideration of Professor Very's letter in SCIENCE of January 5, I wish only to bring to the attention of the readers of SCIENCE section 6 of the Weeks Act, which has been interpreted to require an actual examination by the Geological Survey and a report based thereon which shall consist of a showing of facts rather than an expression of opinion.

Section 6. That the Secretary of Agriculture is hereby authorized and directed to examine, locate and recommend for purchase such lands as in his judgment may be necessary to the regulation of the flow of navigable streams, and to report to the National Forest Reservation Commission the results of such examinations: *Provided*, That before any lands are purchased by the National Forest Reservation Commission said lands

shall be examined by the Geological Survey and a report made to the Secretary of Agriculture, showing that the control of such lands will promote or protect the navigation of streams on whose watersheds they lie.

Those who are familiar with the eventful history leading up to the passage of the Weeks Act know that the principle invoked in section 6 was absolutely essential both to insure the constitutionality of the measure and to secure its passage. The administrative officer, however keenly he may appreciate the spirit which encouraged the movement for the preservation of the Appalachian forests, can not disregard the plain letter of the law on the statute book.

GEO. OTIS SMITH

U. S. GEOLOGICAL SURVEY

SUGGESTIONS FOR THE CLEVELAND MEETING

TO THE EDITOR OF SCIENCE: Regarding the preparations for the meeting of the American Association for the Advancement of Science at Cleveland next year, I desire to suggest the advisability of concentrating the places of meeting so far as practicable, in order that the meeting rooms may be more conveniently found, and persons who wish to pass from one meeting place to another in order to hear a large number of papers read, may be able to do so.

Much of the benefit of these meetings depends on easy access afforded them. For this reason, the best arrangements in many years was that provided in the Central High School at St. Louis. There the basement, and the first- and second-floor classrooms were used for the different sections. Geographers could in a minute's time pass out of their meeting place to hear a paper in the session of the economist and statistician, or *vice versa*. Strangers coming in the building found the directory at the entrance, which told where each section was meeting and the room. There was no wandering about the campus, as at Chicago where some of the sections were located on the third floor of buildings; nor was there any fear of intrusion or collision with professors who had classes to hear, as at the Institute of Technology, Boston; nor was

there any wandering about the streets to find where particular sections met, as in Baltimore.

A central building with wide hallways, the posting of a large directory at some outside point on a thoroughfare and the placarding of rooms, with the placard standing at right angles to the door when closed, with somebody at hand to make additional placards as needed—these suggestions seem to me worth while considering to help make our Cleveland meeting one of the best, if not the best on record.

JOHN FRANKLIN CROWELL

CHROMOSOMES IN WHEAT AND RYE

IN my paper entitled "A Theory of Mendelian Phenomena"¹ I referred to rye as having a small number of chromosomes—"six, I believe," while wheat has "40 or more," and called attention to a possible relation of these supposed facts to the great difference in variability of these two species. This reference to chromosome numbers was made on the basis of a statement made to me some years ago by a student who had made some studies of the subject. Mr. Orland E. White, of the Bussey Institution, calls my attention to the studies of Overton and of Koerniche, which indicate that wheat has sixteen chromosomes (2X number).

W. J. SPILLMAN

WASHINGTON, D. C.

HOW A FALLING CAT TURNS OVER

TO THE EDITOR OF SCIENCE: In your last issue Professor W. S. Franklin mentions having given a valid explanation of how a cat is able to light on his feet when he is dropped back downwards. He does not state what this explanation was; but gives in full a different valid explanation offered by Professor J. F. Hayford. No statement is made as to which explanation agrees with the actual performance of the cat, so it may be of interest to call attention to a set of kinematograph pictures of a falling cat, published as Plate II. of H. Crabtree's "Spinning Tops and Gyroscopic Motion." These pictures corroborate

¹ American Breeders' Association, Report VI.

fully the following explanation given in the accompanying text:

"Let us regard the cat as made up of a fore part and a hind part, whose moments of inertia I_1 , I_2 are equal when the legs are fully extended at right angles to the body. The photographs given in Plate II. show that it first contracts its fore legs (thereby making I_1 less than I_2) and then turns its fore part round. This latter action necessitates the hind part being turned in the opposite direction (since the total angular momentum about the axis is zero) but to a less extent, since I_1 is greater than I_2 . The animal then contracts its hind legs, extends its forelegs, and gives its hind part a turn. This necessitates the fore part being turned in the reverse direction but, again, to a less extent, since I_1 is now greater than I_2 . It will thus be seen that by continued action of this kind the cat can turn itself through any required angle, though at no time has it any angular momentum about its 'axis.'"

The explanation offered by Professor Hayford, although a possible one, accordingly does not agree with the actual performance of a cat, as observed by photography.

SCIENTIFIC BOOKS

The Wilderness of the Upper Yukon: A Hunter's Explorations for Wild Sheep in Sub-Arctic Mountains. By CHARLES SHELTON. New York, Charles Scribner's Sons. 1911. 8vo. Pp. xxi + 354; 4 colored and 46 half-tone plates; 4 maps, one in colors.

The distribution and relationships of the mountain sheep of Canada and Alaska present one of the most interesting and puzzling problems in North American mammalogy. For the purpose of obtaining more definite information on this subject Mr. Sheldon, a hunter-naturalist of well-known qualifications for such a task, spent the seasons of 1904 and 1905 in the Northern Rockies, exploring the Ogilvie, the Selwyn and Plateau mountains and the Watson River country in 1904, and

the Pelly, Rose and Glenlyon mountains in 1905. As a narrative of exploration in practically new fields, the book is an important contribution to our knowledge of the physical conditions and natural history of the region traversed, aside from its bearing upon the special quest for which these journeys were undertaken. Its excellent literary form, its abundant and admirable illustrations and the author's enthusiasm and sympathy with his surroundings, add a value and a charm to his pages unusual in books of hunting adventure. Maps are given of the districts traversed, excellent half-tones illustrate scenic features and there are four colored plates from drawings by Carl Rungius of sheep and other big game.

The sheep of northern Canada and Alaska are quite different from the well-known bighorn of the Rocky Mountains of southern Canada, the United States and northern Mexico. The first northern form to become scientifically known was the *Ovis dalli* described by E. W. Nelson in 1884 from specimens collected in the upper Yukon region of Alaska. This sheep is pure white at all seasons except for adventitious staining from soil or vegetation; it is smaller and has less massive horns than the various forms of the Rocky Mountain bighorn.

In 1897 a black form was described as *Ovis stonei* from specimens obtained in the Cheonee Mountains south of the Stikine River in northern British Columbia. Although the Alaska form is pure white, and the other so dark colored as to be known as the black sheep, the structural differences that characterize them are slight and inconstant.

A few years later (in 1901) a sheep intermediate in coloration between the white and black sheep was described as *Ovis fannini*, based on specimens collected near Dawson City. As the sheep of this general region became better known it was found that the sheep of the *fannini* type were very unstable in respect to coloration and were apparently intergrades between the white form of Alaska, the Yukon and Northwest territories and the black form of northern British Columbia.

This was about the sum of our knowledge of these sheep when Mr. Sheldon set out in 1904 and 1905 to make a special study of the sheep question of the northern Rockies, and to trace out their geographical and physical relationships. Chapter XX. of this book gives a summary of the results of his two seasons' work, and is illustrated by a map in colors showing the known distribution of the white and black sheep of Canada and Alaska, their areas of intergradation and the phases characteristic of special districts. Facing the map are half-tone figures of nine stages of color variation, with explanatory text. The subject is thus graphically and clearly illustrated by the distribution map, the facing explanatory text and shaded figures. The area embraced extends from about latitude 55° to latitude 70°. In Alaska, from the Arctic coast south to latitude 60°, and in Yukon Territory and northeastward in the Mackenzie Mountains to about latitude 62° (generally speaking), the sheep are pure white, except in the Tanana Hills south of the Yukon River, where the white coat is varied with a few black hairs and slight indications of the color pattern of the *fannini* type; in British Columbia south of the Stikine River the sheep are uniformly black; but over an intervening region of from approximately six hundred and fifty miles north and south and about one hundred and fifty to two hundred miles east and west, "there is no area in which the color of the sheep is uniform."

Mr. Sheldon indicates on his map five areas (*a*, *b*, *c*, *d*, *e*) where the sheep are either pure white (*a*), or black (*e*), or are of intermediate or mixed shades (*b*, *c*, *d*); the *b* grade is nearly white, the *d* grade nearly black, *c* being the middle phase or the *fannini* type, which is intermediate geographically as well as in color.

The facts of intergradation are thus forcibly and clearly presented—an intergradation continuous and gradual from one extreme phase to the other through a vast expanse of country. The cause of this extensive and gradual merging of these two widely diverse color types of sheep is not so easily demonstrable. Has it

resulted from interbreeding or is it due to environment? Mr. Sheldon favors the former hypothesis, but admits the possibility of its having been "produced by subtle and indeterminate changes of environment to a much greater extent than the facts seem to me [him] to warrant."

The large size of these animals and the striking color differences between the extreme phases that are thus shown to intergrade render this an impressive instance of intergradation, but parallel cases, though less striking, in other animals usually seem explainable satisfactorily, and in many instances beyond question, on the hypothesis of the action of diverse conditions of environment. But whatever conclusion may finally be reached as to the cause, great credit is due Mr. Sheldon for his contribution of facts through a successful reconnoissance of the almost inaccessible haunts of the sheep in the Northern Rockies where lay the key to the problem—an undertaking few would have the hardihood to project or the endurance and persistence to accomplish. Besides the facts of variation and range already outlined, his contribution to the life-history of these animals is of noteworthy importance, while the wide range of individual variation among members of the same herd, not only as regards coloration, but in respect to size, shape and curvature of the horns is noted in detail. He has also presented to the National Museum the large series of specimens of sheep obtained by him on his expeditions which go far to substantiate the facts of intergradation recorded and illustrated in his book, which may be read with equal interest by the naturalist, the big game hunter and the general reader.

J. A. ALLEN

Principia Mathematica. By ALFRED NORTH WHITEHEAD, Sc.D., F.R.S., Fellow and Lecturer of Trinity College, Cambridge, and BERTRAND RUSSELL, M.A., F.R.S., Lecturer and late Fellow of Trinity College, Cambridge. Cambridge University Press. 1910. Vol. I., pp. xiii + 666.

Mathematicians, many philosophers, logicians and physicists, and a large number of other people are aware of the fact that mathematical activity, like the activity in numerous other fields of study and research, has been in large part for a century distinctively and increasingly critical. Every one has heard of a critical movement in mathematics and of certain mathematicians distinguished for their insistence upon precision and logical cogency. Under the influence of the critical spirit of the time mathematicians, having inherited the traditional belief that the human mind can know some propositions to be true, convinced that mathematics may not contain any false propositions, and nevertheless finding that numerous so-called mathematical propositions were certainly not true, began to reexamine the existing body of what was called mathematics with a view to purging it of the false and of thus putting an end to what, rightly viewed, was a kind of scientific scandal. Their aim was truth, not the whole truth, but nothing but truth. And the aim was consistent with the traditional faith which they inherited. They believed that there were such things as self-evident propositions, known as axioms. They believed that the traditional logic, come down from Aristotle, was an absolutely perfect machinery for ascertaining what was involved in the axioms. At this stage, therefore, they believed that, in order that a given branch of mathematics should contain truth and nothing but truth, it was sufficient to find the appropriate axioms and then, by the engine of deductive logic, to explicate their meaning or content. To be sure, one might have trouble to "find" the axioms and in the matter of explication one might be an imperfect engineer; but by trying hard enough all difficulties could be surmounted for the axioms existed and the engine was perfect. But mathematicians were destined not to remain long in this comfortable position. The critical demon is a restless and relentless demon; and, having brought them thus far, it soon drove them far beyond. It was discovered that an axiom of a given set could be replaced by its contradictory and

that the consequences of the new set stood all the experiential tests of truth just as well as did the consequences of the old set, that is, perfectly. Thus belief in the self-evidence of axioms received a fatal blow. For why regard a proposition self-evident when its contradictory would work just as well? But if we do not know that our axioms are true, what about their consequences? Logic gives us these, but as to their being true or false, it is indifferent and silent.

Thus mathematics has acquired a certain modesty. The critical mathematician has abandoned the search for truth. He no longer flatters himself that his propositions are or can be known to him or to any other human being to be true; and he contents himself with aiming at the correct, or the consistent. The distinction is not annulled nor even blurred by the reflection that consistency contains immanently a kind of truth. He is not absolutely certain, but he believes profoundly that it is possible to find various sets of a few propositions each such that the propositions of each set are compatible, that the propositions of such a set imply other propositions, and that the latter can be deduced from the former with certainty. That is to say, he believes that there are systems of coherent or consistent propositions, and he regards it his business to discover such systems. Any such system is a branch of mathematics. Any branch contains two sets of ideas (as subject matter, a third set of ideas are used but are not part of the subject matter) and two sets of propositions (as subject matter, a third set being used without being part of the subject): a set of ideas that are adopted without definition and a set that are defined in terms of the others; a set of propositions adopted without proof and called assumptions or principles or postulates or axioms (but not as true or as self-evident) and a set deduced from the former. A system of postulates for a given branch of mathematics—a variety of systems may be found for a same branch—is often called the foundation of that branch. And that is what the layman should think when, as occasionally happens,

he meets an allusion to the foundation of the theory of the real variable, or to the foundation of Euclidean geometry or of projective geometry or of *Mengenlehre* or of some other branch of mathematics. The founding, in the sense indicated, of various distinct branches of mathematics is one of the great outcomes of a century of critical activity in the science. It has engaged and still engages the best efforts of men of genius and men of talent. Such activity is commonly described as fundamental. It is very important, but fundamental in a strict sense it is not. For one no sooner examines the foundations that have been found for various mathematical branches and thereby as well as otherwise gains a deep conviction that these branches are constituents of something different from any one of them and different from the mere sum or collection of all of them than the question supervenes whether it may not be possible to discover a foundation for mathematics itself such that the above-indicated branch foundations would be seen to be, not fundamental to the science itself, but a genuine part of the superstructure. That question and the attempt to answer it are fundamental strictly. The question was forced upon mathematicians not only by developments within the traditional field of mathematics, but also independently from developments in a field long regarded as alien to mathematics, namely, the field of symbolic logic. The emancipation of logic from the yoke of Aristotle very much resembles the emancipation of geometry from the bondage of Euclid; and, by its subsequent growth and diversification, logic, less abundantly perhaps but not less certainly than geometry, has illustrated the blessings of freedom. When modern logic began to learn from such a man as Leibniz (who with the most magnificent expectations devoted much of his life to researches in the subject) the immense advantage of the systematic use of symbols, it soon appeared that logic could state many of its propositions in symbolic form, that it could prove some of these, and that the demonstration could be conducted and expressed in the language of symbols. Evidently such a

logic looked like mathematics and acted like it. Why not call it mathematics? Evidently it differed from mathematics in neither spirit nor form. If it differed at all, it was in respect of content. But where was the decree that the content of mathematics should be restricted to this or that, as number or space? No one could find it. If traditional mathematics could state and prove propositions about number and space, about relations of numbers and of space configurations, about classes of numbers and of geometric entities, modern logic began to prove propositions about propositions, relations and classes, regardless of whether such propositions, relations and classes have to do with number and space or any other specific kind of subject. At the same time what was admittedly mathematics was by virtue of its own inner developments transcending its traditional limitations to number and space. The situation was unmistakable: traditional mathematics began to look like a genuine part of logic and no longer like a separate something to which another thing called logic applied. And so modern logicians by their own researches were forced to ask a question, which under a thin disguise is essentially the same as that propounded by the bolder ones among the critical mathematicians, namely, is it not possible to discover for logic a foundation that will at the same time serve as a foundation for mathematics as a whole and thus render unnecessary (and strictly impossible) separate foundations for separate mathematical branches?

It is to answer that great question that Messrs. Whitehead and Russell have written "*Principia Mathematica*"—a work consisting of three large volumes, the first being in hand, the second and third soon to appear—and the answer is affirmative. The thesis is: it is possible to discover a small number of ideas (to be called primitive ideas) such that all the other ideas in logic (including mathematics) shall be definable in terms of them, and a small number of propositions (to be called primitive propositions) such that all other propositions in logic (including mathematics) can be demonstrated by means of

them. Of course, not all ideas can be defined—some must be assumed as a working stock—and those called primitive are so called merely because they are taken without definition; similarly for propositions, not all can be proved, and those called primitive are so called because they are assumed. It is not contended by the authors (as it was by Leibniz) that there exist ideas and propositions that are absolutely primitive in a metaphysical sense or in the nature of things; nor do they contend that but one sufficient set of primitives (in their sense of the term) can be discovered. In view of the immeasurable wealth of ideas and propositions that enter logic and mathematics, the authors' thesis is very imposing; and their work borrows some of its impressiveness from the magnificence of the undertaking. It is important to observe that the thesis is not a thesis of logic or of mathematics, but is a thesis about logic and mathematics. It can not be proved syllogistically; the only available method is that by which one proves that one can jump through a hoop, namely, by actually jumping through it. If the thesis be true, the only way to establish it as such is to produce the required primitives and then to show their adequacy by actually erecting upon them as a basis the superstructure of logic (and mathematics) to such a point of development that any competent judge of such architecture will say: "Enough! I am convinced. You have proved your thesis by actually performing the deed that the thesis asserts to be possible."

And such is the method the authors have employed. The labor involved—or shall we call it austere and exalted play?—was immense. They had predecessors, including themselves. Among their earlier works Russell's "Principles of Mathematics" and Whitehead's "Universal Algebra" are known to many. The related works of their predecessors and contemporaries, modern critical mathematicians and modern logicians, Weierstrass, Cantor, Boole, Peano, Schröder, Peirce and many others, including their own former selves, had to be digested, assimilated and transcended. All this was done, in the course

of more than a score of years; and the work before us is a noble monument to the authors' persistence, energy, acumen and idealism. A people capable of such a work is neither crawling on its belly nor completely saturated with commercialism nor wholly philistine. There are preliminary explanations in ordinary language and summaries and other explanations are given in ordinary language here and there throughout the book, but the work proper is all in symbolic form. Theoretically the use of symbols is not necessary. A sufficiently powerful god could have dispensed with them, and, unless he were a divine spendthrift, he would have done so, except perhaps for the reason that whatever is feasible should be done at least once in order to complete the possible history of the world. But whilst the employment of symbols is theoretically dispensable, it is, for man, practically indispensable. Many of the results in the work before us could not have been found without the help of symbols, and even if they could have been thus found, their expression in ordinary speech, besides being often unintelligible, owing to complexity and involution, would have required at least fifteen large volumes instead of three. Fortunately the symbology is both interesting and fairly easy to master. The difficulty inheres in the subject itself.

The initial chapter, devoted to preliminary explanations that any one capable of nice thinking may read with pleasure and profit, is followed by a chapter of 30 pages dealing with "the theory of logical types." Mr. Russell has dealt with the same matter in volume 30 of the *American Journal of Mathematics* (1908). One may or may not judge the theory to be sound or adequate or necessary and yet not fail to find in the chapter setting it forth both an excellent example of analytic and constructive thinking and a worthy model of exposition. The theory, which, however, is recommended by other considerations, originated in a desire to exclude from logic automatically by means of its principles what are called illegitimate totalities and therewith a subtle variety of contradiction and vicious circle fallacy that, owing their presence to the

non-exclusion of such totalities, have always infected logic and justified skepticism as to the ultimate soundness of all discourse, however seemingly rigorous. (Such theoretic skepticism may persist anyhow, on other grounds.) Perhaps the most obvious example of an illegitimate totality is the so-called class of all classes. Its illegitimacy may be shown as follows. If A is a class (say that of men) and E is a member of it, we say, E is an A . Now let W be the class of all classes such that no one of them is a member of itself. Then, whatever class x may be, to say that x is a W is equivalent to saying that x is not an x , and hence to say that W is a W is equivalent to saying that W is not a W ! Such illegitimate totalities (and the fallacies they breed) are in general exceedingly sly, insinuating themselves under an endless variety of most specious disguises, and that, not only in the theory of classes but also in connection with every species of logical subject-matter, as propositions, relations and propositional functions. As the propositional function—any expression containing a real (as distinguished from an apparent) variable and yielding either non-sense or else a proposition whenever the variable is replaced by a constant term—is the basis of our authors' work, their theory of logical types is fundamentally a theory of types of propositional functions. It can not be set forth here nor in fewer pages than the authors have devoted to it. Suffice it to say that the theory presents propositional functions as constituting a summitless hierarchy of types such that the functions of a given type make up a legitimate totality; and that, in the light of the theory, truth and falsehood present themselves each in the form of a systematic ambiguity, the quality of being true (or false) admitting of distinctions in respect of order, level above level, without a summit. When Epimenides, the Cretan, says that all statements of Cretans are false, and you reply that then his statement is false, the significance of "false" here presents two orders or levels; and logic must by its machinery automatically prevent the possibility of confusing them.

Next follows a chapter of 20 pages, which all philosophers, logicians and grammarians ought to study, a chapter treating of Incomplete Symbols wherein by ingenious analysis it is shown that the ubiquitous expressions of the form "the so and so" (the "the" being singular, as "the author of Waverley," "the sine of a ," "the Athenian who drank hemlock," etc.) do not of themselves denote anything, though they have contextual significance essential to discourse, essential in particular to the significance of identity, which, in the world of discourse, takes the form of " a is the so and so" and not the form of the triviality, a is a .

After the introduction of 88 pages, we reach the work proper (so far as it is contained in the present volume), namely, Part I.: Mathematical Logic. Here enunciation of primitives is followed by series after series of theorems and demonstrations, marching through 578 pages, all matter being clad in symbolic garb, except that the continuity is interrupted here and there by summaries and explanations in ordinary language. Logic it is called and logic it is, the logic of propositions and functions and classes and relations, by far the greatest (not merely the biggest) logic that our planet has produced, so much that is new in matter and in manner; but it is also mathematics, a prolegomena to the science, yet itself mathematics in the most genuine sense, differing from other parts of the science only in the respects that it surpasses these in fundamentality, generality and precision, and lacks traditionality. Few will read it, but all will feel its effect, for behind it is the urgency and push of a magnificent past: two thousand five hundred years of record and yet longer tradition of human endeavor to think aright.

C. J. KEYSER

COLUMBIA UNIVERSITY

A LETTER OF LAMARCK

LETTERS of Lamarck are not often found. M. Landrieux, who has recently published a life of Lamarck, states that "one can count the number of his letters which have come

down to us,"¹ and that "even his autographs are exceedingly rare."

It is of interest, therefore, that another letter in the hand of Lamarck has been discovered in Paris (it is now in my possession), and as it contains several data regarding his life, it may be worthy of publication. It reads as follows:

PARIS ce 16 floréal au 5 de la Rep.
Lamarck professeur au Museum d'hist. naturelle
Au Citoyen Cyalis Lavaux Directeur de la
1^{ère} division des domaines
Citoyen

ayant reçu de Songeons, département de l'oise, l'avis que la vente des biens que j'ai Soumissonnés étoit Suspendue et qu'on avoit méconnue l'autorité du Ministre des finances, j'ai eu l'honneur de vous faire passer une lettre par laquelle je me Suis plaint de la Conduite du département à cet égard. j'apprends en ce moment que la personne qui m'a fait passer cet avis m'a trompé, et que le département de l'oise n'a encore pris aucun arrêté qui me fut préjudiciable. je me hâte de vous en instruire pour vous prier de ne donner aucune Suite à la lettre que j'ai eu l'honneur de vous faire passer.

quand le Ministre de l'interieur aura fait passer à Son Colleague le Ministre des finances les Conditions de la vente de ma Collection, je me recommande à votre bienveillance que vous avez déjà bien voulu me promettre, et pour laquelle je vous prie d'agréer ma vive reconnaissance et mes Salutations fraternelles.

LAMARCK

It will be seen from the above details that Lamarck, like many members of his class, was troubled in matters of property during the upheaval of the revolution. He had maintained his post, poor as it was, in the Jardin des Plantes in 1790, and had made a strong plea for a reorganization of this institution under the republican régime: he had even (1793) gained the day and during the most democratic epoch, he was distinguished as one of the first professors placed in charge of the collections of the Jardin des Plantes. The present letter shows, none the less, that in 1794 Lamarck was concerned about his property at Songeons.

¹ "Lamarck le Fondateur du Transformism," 1909, p. 105.

The authorities had not, however, as he later ascertained, confiscated it, and ordered its sale. Still, times were bad and he was probably in financial straits, since he took the opportunity in the same letter to refer to the matter of the sale of his (private) collection, and to "pull a wire" more or less insistently.

BASHFORD DEAN

SPECIAL ARTICLES

THE APPARENT ANTAGONISM BETWEEN ELECTROLYTES AND NONCONDUCTORS

1. In a publication contained in SCIENCE, Vol. XXXIV., No. 887, pp. 928, Sumner makes the following statement: "Loeb's assertion that 'salts alone have such antagonistic effects' certainly does not apply to adult fishes. I need only call attention to the fact that cane-sugar solutions of certain strengths were found by me to very clearly defer the fatal action of the copper salts, both upon *Fundulus heteroclitus* and upon certain fresh-water species."

Thirteen years ago I pointed out the fundamental difference between the influence of electrolytes and nonelectrolytes upon life phenomena and in later publications called attention to the fact that this difference indicated an interaction between the electrolytes and colloids, especially the proteins, of the cells, which did not exist between nonelectrolytes and the same colloids of the cells. The further development of colloid chemistry and biology has shown that this conclusion was correct and fruitful. The fact that the toxic action of electrolytes upon the cells can be antagonized by electrolytes only is a special case of this more general rule. In 1902 Gies and I published an apparent exception to this rule, namely, that the toxic action of $ZnSO_4$ upon *Fundulus* eggs could be inhibited through the addition of cane-sugar; but we pointed out that in this case there is no antagonistic action between $ZnSO_4$ and cane-sugar in regard to the colloids of the egg (or membrane) but a chemical reaction between $ZnSO_4$ and cane-sugar which leads to the formation of zinc saccharate, and consequently to a diminution of the Zn ions in solu-

tion. Five years later Sumner published his observations that the action of copper salt can be deferred through the addition of cane-sugar, which is of course similar to the observation by Gies and myself. In the case of the antagonization of ZnSO_4 by another electrolyte we are, however, dealing with the action of both electrolytes on the same colloid.

2. Sumner states also that distilled and fresh water are toxic for *Fundulus* and that there exists an antagonism between distilled water and salts for these fish. The fact that a number of *Fundulus* can live a long time (if not indefinitely) in distilled water and that these fish, if they become landlocked, can live indefinitely in fresh water indicates that the distilled or fresh water are not in themselves toxic for these animals but that the toxic effect occasionally (but not always) observed is due to an inconstant or quantitatively varying constituent of the water. This constituent may be a parasite, or it may be a substance given off by the fish itself, *e. g.*, CO_2 . Wasteneys and I have recently found that CO_2 may produce the same changes on the skin and the gills of the fish as those produced by mineral acids; and that, as in the latter case, the etching effects of the CO_2 may be counteracted through the addition of a neutral salt. The beneficial effect of the addition of some salt to the fresh or the distilled water, therefore, indicates that the salt either kills certain parasites contained or developed in the distilled water, or antagonizes the toxic effects of some electrolyte, *e. g.*, carbonic acid, if its concentration exceeds a certain limit, as it possibly did in some or all of Sumner's experiments.

JACQUES LOEB

ROCKEFELLER INSTITUTE

THE PERMEABILITY OF PROTOPLASM TO IONS AND THE THEORY OF ANTAGONISM

EVIDENCE was recently presented which showed¹ that a great variety of salts readily enter living cells and that antagonism between salts may be due to the fact that they mutu-

ally hinder or prevent each other from penetrating the protoplasm.

In these experiments plasmolysis was the criterion of penetration. Plasmolysis shows which salts enter and how rapidly, but does not indicate whether it is the ions or only undissociated molecules which penetrate the cell. To decide this question experiments were performed to test the electrical conductivity of living tissues in various solutions. The results agree in showing most conclusively that ions readily penetrate living protoplasm and that many ions which penetrate quite rapidly in pure solutions may be hindered or prevented from going in by the addition of small amounts of CaCl_2 or other salts.

To obtain reliable results in conductivity experiments material should be used which is not injured by weak currents or by other experimental conditions. It is desirable that the amount of space between the cells be constant so that the current which passes between the cells may be a constant fraction (as small as possible) of that which actually traverses the living protoplasm. The current should pass through a large number of thin sheets of living tissue, separated by thin films of solution. The penetration of various ions may then be studied by merely changing the solution. If the material is in thin sheets the ions are forced by the alternating current to pass in and out of a great extent of protoplasmic surface; this is of great importance, since the larger the surface the more reliable the measurement. The sheets of living tissue should be sufficiently rigid to permit manipulation and to endure without injury pressure sufficient to pack them firmly together so that the films of solution which separate them may be as thin as possible.

All these conditions are admirably fulfilled by the common kelps of the Atlantic coast (species of *Laminaria*). This material was accordingly used throughout the investigations.

Disks about 13 mm. in diameter were cut from the fronds by means of a cork-borer (the average thickness of the frond was about 0.5 mm.). From 100 to 200 of these disks

¹ SCIENCE, N. S., 34: 187, 1911.

were packed together (like a roll of coins) into a solid cylinder from 50 mm. to 100 mm. long. They were firmly held in place by glass rods arranged to make a hollow cylinder which closely fitted over the outside of the solid cylinder of tissue. Spaces between the rods allowed free access of the solution to the living tissue. At each end of the cylinder of tissue was placed a block of hard rubber containing a platinum electrode covered with platinum black; by means of a screw these blocks could be pressed with considerable force against the opposite ends of the cylinder of living tissue. The only substances which came into contact with the solution were hard rubber, glass, the electrodes and the living tissue. Details of construction will be given in a subsequent paper.

The current after leaving the electrodes traversed the solution for a very short distance and then passed directly into the living tissue. The same solution which bathed the electrodes was also present between the disks of living tissue in the form of thin films. The surface in and out of which ions were forced by the current amounted to from 26,500 to 53,000 sq. mm.

The measurements were made in the usual manner by means of a Wheatstone bridge. The solutions were brought to the same temperature before measuring except that in the case of small deviations the proper correction was made.

The usual method of procedure was to place the cylinder of disks in the solution, clamp the electrode carriers firmly against both ends of it, lift it out of the solution and read the resistance as soon as the superfluous liquid had drained from the tissue.

A preliminary series of experiments showed that the material remained to an extraordinary degree uninjured by the action of the currents employed as well as by the additional treatment involved in the experiments. In the first experiments the material was usually left immersed in sea water in the apparatus for 24 hours. During this period 12 readings were taken (the current passing for about two minutes each time) and the disks were

12 times taken out and then replaced in the apparatus. At the end of the 24 hours the resistance to the current remained unchanged (if injury had occurred the resistance would have been diminished) and there was no indication either macroscopic or microscopic that the cells were injured.

If the plasma membrane and the cell wall presented no obstacle to the passage of ions we should expect the resistance of a cylinder of living tissue to be practically that of a similar cylinder full of sea water. It was found that a cylinder of living tissue had a resistance of 1,100 ohms (all the figures given in this paper refer to readings taken between 18° C. and 18.2° C.) while that of a cylinder of sea water of equal size was 320 ohms. To ascertain whether this excess of resistance was due to living protoplasm or to cell walls the protoplasm was killed by adding sufficient formalin to the sea water to make a 2 per cent. solution. In other experiments the disks were killed by careful drying. In all cases the resistance after killing fell to about 320 ohms. These experiments demonstrated in the clearest manner that the ions penetrated very much less rapidly into living cells than into dead protoplasm or into cell walls.

Experiments were then made to determine the rate of penetration of various ions. As the treatment was the same in all cases it will suffice to describe a typical experiment dealing with NaCl and CaCl₂.

The material was first tested in sea water and found to have a resistance of 1,100 ohms. After remaining four hours in sea water the resistance was unchanged. The material was then transferred to NaCl .52 *M* which had the same temperature as the sea water and the same conductivity (as determined by numerous careful tests). The electrode carriers were unclamped and moved apart. Each disk was then seized in turn by the forceps and moved back and forth in the solution so as to wash out the sea water and replace it by the solution of pure NaCl. This was repeated several times. It was thus possible to rinse each disk thoroughly in the solution without removing it from the apparatus or changing

its position in the series of disks which composed the cylinder. The mere act of rinsing the disks in this way and then reclamping the electrodes made only slight changes in the reading.

After remaining five minutes in NaCl .52 *M* the resistance had dropped to 1,000 ohms; after ten minutes to 890 ohms; after fifteen minutes to 780 ohms; after sixty minutes to 420 ohms. It continued to fall steadily until it reached 320 ohms, at which point it remained stationary; it then had practically the conductivity of sea water. On replacing in sea water it did not recover any of its resistance, even after standing for several days. It should be noted that the solution of NaCl employed is nearly isotonic with sea water and that none of the observed effects could be due to osmotic action.

Further experiments showed that if the material was removed from NaCl solution and placed in sea water as soon as its resistance had fallen about one hundred ohms below the original resistance it quickly regained its original resistance and remained unchanged for a long time.

It is therefore evident that pure NaCl produces a very rapid decrease in resistance which, up to a certain point, is reversible.

A very striking contrast is obtained by placing living tissue in a solution of CaCl_2 having the same conductivity as sea water. The resistance then rises rapidly to a maximum (very often in the first fifteen minutes from 1,100 ohms to 1,750 ohms) and remains practically stationary for some hours. After this it slowly sinks and finally reaches about 320 ohms, which is the resistance of an equal amount of sea water. If, however, it be returned to sea water shortly after it has reached its maximum it soon regains its original resistance and remains for a long time (in sea water) practically unchanged. The rise in resistance caused by CaCl_2 is in no way due to its action on the cell walls, for dead tissue shows no rise.

It is therefore evident that CaCl_2 produces a very rapid increase in resistance, which is reversible.

What is the effect of combining NaCl and CaCl_2 in the proportions in which they exist in sea water? This question has great theoretical and practical interest in view of the fact that CaCl_2 is known to antagonize the toxic action of NaCl in the most striking way. To answer this question the following experiment was performed. To 1,000 c.c. NaCl 1 *M* there was added 15 c.c. CaCl_2 1 *M*; the mixture was then diluted until it had the same conductivity as sea water. On placing living tissue in this mixture it neither gained nor lost in resistance and even after twenty-four hours had the same resistance as at the start.

It is therefore evident that the entrance of the ions of NaCl is greatly hindered by the presence of very small amounts of CaCl_2 and that this may explain the antagonistic action of CaCl_2 on NaCl.

Further experiments showed that such salts as KCl, MgCl_2 , CsCl, RbCl, LiCl, NH_4Cl , NaBr, NaI, NaNO_3 , Na_2SO_4 and Na-acetate act in general like NaCl (though with different degrees of rapidity) while BaCl_2 and SrCl_2 act like CaCl_2 .

It might be supposed that some of these effects are due to expansion or contraction of the cells under the influence of the salts, but microscopic observation showed that this was not the case except only that when a cell is injured by the salt a contraction (which I have elsewhere called false plasmolysis) may take place. But as the fall in resistance is already great before any such contraction begins and as the contraction is in any case too small to account for more than a small per cent. of the decrease in resistance it may be regarded as at best a secondary factor which is absent until the resistance has reached a low point and which is almost negligible beyond that point.

It might be supposed that the change in resistance is due to causes which operate in the interior of the cell rather than in the plasma membrane, but this is opposed to a variety of evidence which can not be discussed here.

Two hypotheses may be formed regarding

the increase of resistance which is observed when the tissue is transferred from $\text{NaCl} + \text{CaCl}_2$ to pure CaCl_2 of the same conductivity. On one hypothesis the plasma membrane would retain its normal properties after the transfer but would show increased resistance because it is normally less permeable to the ions of CaCl_2 than to the ions of NaCl .

On the other hypothesis the plasma membrane would suffer a change in its properties as the result of the transfer. The facts strongly favor this hypothesis. I will mention only a few. Visible changes in the outer layer of the protoplasm are produced by CaCl_2 (and many other substances) and this makes it probable that the plasma membrane suffers change. Alum, which is known to alter the properties of many colloids (*e. g.*, in tanning), when added in solid form to the sea water greatly increases the resistance of the protoplasm although it greatly decreases the resistance of the sea water. In this case the only explanation is that the permeability of the plasma membrane is altered. On the other hand it is clear that the large number of substances which produce irreversible decrease of resistance must also alter the plasma membrane.

It seems probable therefore that a great variety of substances alter the plasma membrane so as to increase or decrease its permeability.

It may be pointed out that these results are precisely what should be expected if the antagonistic action of salts is due, as Loeb has suggested, to the fact that they hinder each other from penetrating the protoplasm. It is quite clear from the experiments that CaCl_2 , SrCl_2 , and BaCl_2 in small amounts are able to hinder very greatly the entrance of the ions of NaCl . The mechanism of this action is not fully understood, but I may state that CaCl_2 , BaCl_2 , and SrCl_2 bring about visible changes in the plasma membrane which are entirely different from those produced by such salts as NaCl . It is hoped that a further study of these visible changes may throw light on this question.

Previous experiments on plasmolysis have

shown essentially similar phenomena and the complete confirmation of the results of one method by those of the other form the most striking proof possible of the facts outlined above.

It may be asked how merely delaying the entrance of a salt can protect the protoplasm against its toxic action. In this connection it may be pertinent to recall the familiar phenomenon of colloid chemistry that a salt which produces marked effects when added suddenly may produce little or no effect when added slowly. It should be noted that there is good evidence to show that the NaCl does not enter the cell alone but is accompanied by CaCl_2 . It is possible that these salts may wholly prevent each other from penetrating internal membranes (*e. g.*, the nuclear membrane) which are of importance in this connection.

The chief conclusions are as follows:

1. Quantitative studies of permeability may be made by a simple and accurate method.
2. Slight changes in the rate of penetration may be observed and accurately measured at very brief intervals.
3. A great variety of anions and kations readily penetrate living protoplasm.
4. Inasmuch as these ions are insoluble in lipid it would appear that Overton's theory of permeability can not be correct.
5. The plasma membrane is readily altered by a variety of substances in a fashion which is easily understood on the hypothesis of a colloid (probably proteid) plasma membrane but which can not be explained on the hypothesis that the plasma membrane is a lipid.
6. The antagonistic action of salts is largely or entirely due to the fact that they hinder or prevent one another from entering the protoplasm.

NOTES ON THE DISTRIBUTION OF THE SOUTH-
EASTERN SALAMANDERS (GEOMYS TUZA AND
ALLIES)

A CHARACTERISTIC feature of many parts of
the pine forests of the coastal plain of Georgia,

Alabama and Florida is the common occurrence of small mounds of sand a foot or more in diameter and a few inches high, scattered irregularly over the surface or in more or less evident lines, and usually several feet apart. A traveler from farther northeast, seeing these mounds for the first time, might easily imagine that some one had been driving along with a wagon-load of sand and dumping it out in large shovelfuls. They are seen best in winter and spring, partly because the surrounding vegetation is less conspicuous then, and partly for other reasons.

These diminutive mounds cover the outlets of the burrows of a subterranean rodent, *Geomys Tuza*, which is known throughout its range as the "salamander." (Zoologists have divided the original *G. Tuza* into some half-dozen species and subspecies, but there are no wider gaps between the ranges of the different forms than there are between some colonies of the same species, and they all have essentially the same habits and habitat, so that for the purposes of this discussion it will be most convenient to treat the group as a unit.) The animal feeds on roots, travels entirely underground, as far as known, and very rarely shows itself, in the daytime at least.

While working for the Florida State Geological Survey in 1908-1910 I had occasion to visit every county and to travel on nearly every railroad in that state; and on railroad journeys I usually had nothing better to do than look out of the car-window and make notes on the topography, vegetation and other geographical features. The salamander hills, which certainly constitute one of the topographic features, even if a very insignificant

¹ Dr. C. Hart Merriam in his elaborate monograph of *Geomys* and related genera ("N. Am. Fauna No. 8," p. 112, 1895) characterized this common name as "singularly inappropriate and misleading." But contrary opinions as to its appropriateness have been expressed by Goode (Powell's Report on Colorado River, p. 281, 1875) and Bangs (*Proc. Bost. Soc. Nat. Hist.*, 28, p. 175, 1898); and it is no more misleading than the names cypress, cedar, sycamore and poplar, applied to very different trees in this country from what they are in the old world.

one, thus received their share of attention, and in that way I have accumulated records of hundreds of precise localities for this elusive animal. On plotting these on a map recently some interesting correlations between them and certain other geographical features became evident. In previous years I had visited every county in Georgia and Alabama in which *Geomys* is known, but my notes on its distribution in these two states are much less complete than they are for Florida.

In both Georgia and Alabama the salamander ranges all the way across the coastal plain up to the fall-line, in about latitude 33° 15', but one can travel many miles without seeing any evidences of it, and it is much less abundant in those states and in west Florida than it is in peninsular Florida. The Biological Survey of the U. S. Department of Agriculture has a record² of just one station for it outside of the coastal plain, namely, near Chipley, Georgia.³ In Alabama the only known stations for it north of the latitude of Montgomery seem to be around Kingston, in Autauga County; in the northeastern corner of Hale County; on high pine hills near Lock 14 on the Warrior River, and between Brookwood and Searles. At both of the last-named stations, which are in the upper (northeastern) part of Tuscaloosa County, the salamander hills are found over Carboniferous rocks, but always where there is a thin layer of some unconsolidated coastal plain deposit, presumably the Lafayette, on the surface.

In Florida salamander hills can be seen in abundance at frequent intervals all the way down to a point between Nocatee and Fort Ogden in DeSoto County, about latitude 27° 10', which is about fifty miles farther south than the southernmost station for *Geomys* mentioned by Outram Bangs in his interesting paper on the land mammals of

² Unpublished, but communicated to me by Mr. A. H. Howell.

³ There happens to be also a Chipley in Florida, a more important place than the one in Georgia, and it is barely possible that the specimen in question came from Florida and was ascribed to Georgia by a slip of the pen.

peninsular Florida.⁴ I have seen them in every county in that state except Franklin, Manatee, Lee, Osceola, Brevard, St. Lucie, Palm Beach, Dade and Monroe, all of which were included by Dr. Eugene A. Smith, in his classical paper on the geography of Florida,⁵ in what he called the "pitch-pine, treeless and alluvial region." These counties are all in south Florida with the exception of Franklin, which is in middle and west Florida, over 200 miles from the rest. Dr. Smith admitted that this was not a very homogeneous area, but he grouped these counties together for convenience because they produced almost no cotton (only two bales being reported from that whole area in 1880). The distribution of *Geomys* now furnishes an additional character for distinguishing these counties from the remainder of the state; for I have seen salamander hills in every county included by Dr. Smith in his other two regions, namely, the "long-leaf pine region," and the "oak, hickory and pine upland region." (The counties in Florida are of course more numerous now than they were at the time of the Tenth Census, but it so happens that that does not affect the truth of this statement.)

About a year ago, in a report on the peat deposits of Florida,⁶ the writer divided the state provisionally into fourteen geographical divisions. Of these the lime-sink region and the lake region, near the axis of the peninsula, seem to be the headquarters of the salamander. The animal is not known at all in the East Coast strip or the coast region of West Florida, both of which consist chiefly of modern (active) dunes next to the ocean and ancient (fixed) dunes a little farther back. It occurs in varying degrees of abundance in the remaining divisions, except those south of the latitude of Lake Okeechobee.

⁴ *Proc. Bost. Soc. Nat. Hist.*, 28, p. 176, 1898.

⁵ Tenth Census U. S., 6, pp. 175-257, 1884. This monograph, like those on other southeastern states in the same volume, bears the entirely too modest designation of a report on cotton production.

⁶ *Ann. Rep. Fla. Geol. Surv.*, 3, pp. 201-375, pls. 16-28, January, 1911.

The range of the southeastern salamander⁷ seems to terminate abruptly on the east at the Savannah River, and on the west at the Warrior and the streams which under two or three other names connect that river with the Gulf of Mexico. From all accounts it appears that the various subspecies (or species as some regard them) of this group, which are the only representatives of the genus east of the Wash River and its continuations, nowhere occupy the same territory, but are separated by rivers, which must be almost impassable barriers to an animal which spends its life underground and has no use for water. Indeed it is difficult to imagine how such an animal could ever have crossed any of the large rivers which extend all the way across the coastal plain; but at some time in the past the ancestors of the present salamanders must have crossed at least three such rivers, namely, the Altamaha, Apalachicola and Alabama. (The crossing of the Mississippi and Ohio rivers by members of the genus must have taken place at a much more remote period, judging from the much greater geographical and phylogenetic gap between the species on opposite sides of these rivers.) Mr. Bangs, in his paper already cited, expressed the opinion that *G. Floridanus* is separated from the other forms by the St. Mary's and Suwannee rivers, with Okefinokee Swamp connecting their headwaters. If this is true then the salamanders of middle Florida (i. e., that part of the state between the Suwannee and Apalachicola rivers) must be typical *G. Tuza*, the same as in Georgia. However that may be, salamander hills of exactly identical appearance can be found within a mile or two of each other on opposite sides of the Suwannee, which has almost no swamps where it passes through the lime-sink region.

So much for the areal distribution of our salamander. Some interesting correlations

⁷ According to Dr. Merriam's monograph previously cited, *Geomys Tuza* and its near relatives are confined to the three states already named, but the same common name is also applied to another species which inhabits Arkansas and Louisiana.

between it and certain soils and other environmental factors can now be made. Its hills are almost always in dry sandy loam,* presumably of Pliocene or Pleistocene age. It avoids on the one hand the fertile limestone and clay soils which characterize some parts of the coastal plain, and on the other the hopelessly sterile sands of the shifting dunes along the coast and the "scrub" of the Florida peninsula. It is most abundant in regions where according to the statistical maps in the fifth and sixth volumes of the Tenth Census less than one acre to the square mile was cultivated in cotton in 1880; but in soils which at the present stage of the economic development of the southeastern United States are being appropriated by farmers most rapidly. Being confined to dry soil, it is absent from land which is too damp for cultivation by ordinary methods (as well as that which is too sterile or too rocky). But I have never heard any complaints about its interfering with agricultural operations.

The southeastern salamander seems to be invariably associated with the long-leaf pine (*Pinus palustris*), and it may derive part of its food from the roots of that useful tree. The only known station in the Piedmont region of Georgia, mentioned above, is probably not right in the city of Chipley, but very likely on the Pine Mountains near by, where the rocks and soil are pretty sandy, and long-leaf pine abounds.⁸ The range of our animal is by no means coextensive with that of the long-leaf pine, though, for the tree ranges from Virginia to Texas, as well as considerably farther inland in Georgia and Alabama and a little farther south in Florida than the salamander does. Two other trees usually found in the vicinity of salamander hills, and

having more nearly the same range, are two scrubby oaks, *Quercus Catesbaei* and *Q. cinerea*. Mr. Bangs (*op. cit.*, p. 180) states that Cumberland Island, Georgia, is the only one of the sea-islands (which fringe the coast from about Charleston to Jacksonville) on which a *Geomys* occurs. It is also, to the best of my knowledge and belief, the only one which has *Pinus palustris* and *Quercus Catesbaei* on it; and its geological history must have been somewhat different from that of the others.

Lastly there are some interesting relations between the salamander and forest fires, as was noticed briefly long ago in the papers cited in the first footnote.⁹ Every long-leaf pine forest, without exception, is periodically swept by fire, which burns off the dead herbage and keeps down the underbrush, but does no harm to sound pine trees after they get beyond a certain age. (In prehistoric times these fires, presumably set by lightning, probably did not visit any one spot oftener than once in four or five years, on the average; but now so many fires are set accidentally or purposely by man that few of these forests escape fire longer than a year or two at a time.)¹⁰ The dunes and scrub of Florida, mentioned above, as well as the other extreme, the rich hammocks, have so little herbage that fires are very rare, and in such places there are neither long-leaf pines nor salamanders.

Fires in the southern pine woods are most frequent in late winter and early spring, and the salamanders seem to be most active just about that time. The locality near Lock 14 on the Warrior River, when first discovered on April 15, 1911, had evidently been burned over a few days or weeks previously, and the salamander hills there looked pretty fresh. What is still more interesting, none could be found in precisely similar areas near by

* At the northernmost Alabama stations there is a considerable admixture of gravel in the soil, and it is possible that if specimens could be obtained from these somewhat isolated localities they might be found to differ perceptibly in some characters from the only form at present known in that state, *♂. Tusa Mobilensis*.

⁸ See *Bull. Torrey Bot. Club*, 36, pp. 585-586, 1909.

⁹ The same relation was noticed still earlier by Sir Charles Lyell, the English geologist, in Screven County, Georgia, in the winter of 1841-42. ("Travels in North America," Vol. I., p. 161, 1845.)

¹⁰ In this connection, see *Bull. Torrey Bot. Club*, 38, p. 522, 1911.

which had not been burned recently. The locality was revisited in May and June, during which time there were no more fires, and the salamander hills were gradually settling down and disappearing, no new ones having been made in the interval, apparently." It would be very interesting to know if the related species of the middle northwest, *G. bursarius*," shows a similar reaction to prairie fires.

ROLAND M. HARPER

THE AMERICAN MATHEMATICAL SOCIETY

THE eighteenth winter meeting of the society was held at Columbia University on Wednesday and Thursday, December 27-28, 1911, the program occupying two sessions on each day. The total attendance was about seventy-five, including sixty-three members. President H. B. Fine occupied the chair, being relieved by ex-President H. S. White. The following new members were admitted: Professor Ida Barney, Rollins College; Professor Louis Brand, University of Cincinnati; Professor C. W. Cobb, Amherst College; Professor J. C. Fitterer, University of Wyoming; Mr. G. H. Graves, Columbia University; Dr. Solomon Lefschetz, University of Nebraska; Mr. G. H. Light, Purdue University; Mr. E. S. Palmor, Rutgers College; Professor E. R. Smith, Pennsylvania State College. Eight applications for membership were received. The total membership of the society is now 669, an increase of 27 during the past year.

On Wednesday evening forty-two of the members gathered at the annual dinner at the Murray Hill Hotel. These informal dinners have long been recognized as one of the most attractive features of the meetings.

The treasurer's report shows a balance of \$8,723.89, or deducting outstanding bills, about \$3,200, a slight increase for the year. The income from sales of publications was \$1,513.66. The life membership fund now amounts to \$4,137.17. The number of papers read at all meetings of the year was 180; the total attendance of members was 350. At the annual election 197 votes were cast.

"In June Mr. A. H. Howell set traps in several of these hills, but without catching anything, which seems to indicate that the animals were not working near the surface at that time.

"Since Dr. Merriam's monograph some additional notes on the habits of this species have been published by Mr. C. L. Webster in the *American Naturalist*, 31, pp. 114-120, 1897.

The society's library has increased to 3,840 volumes, beside some 500 unbound dissertations.

At the annual election, which closed on Thursday morning, the following officers and other members of the council were chosen: *Vice-presidents*, H. F. Blichfeldt and Henry Taber; *Secretary*, F. N. Cole; *Treasurer*, J. H. Tanner; *Librarian*, D. E. Smith; *Committee of Publication*, F. N. Cole, E. W. Brown and Virgil Snyder; *Members of the Council* (to serve until December, 1914), A. B. Coble, E. W. Davis, Oswald Veblen and E. B. Wilson.

The following papers were read at this meeting:

W. M. Smith: "A characterization of isogonal and equitangential trajectories."

C. L. E. Moore: "Surfaces in hyperspace which have a tangent line with three-point contact passing through each point."

J. E. Rowe: "How to find a set of invariants for any rational curve of odd order."

J. E. Rowe: "A covariant point of the E^* , and a special canonical form."

R. L. Moore: "On the sufficient conditions that an integral equation of the second kind shall have a continuous solution."

E. B. Wilson: "Some mathematical aspects of relativity."

Edward Kasner: "Families of surfaces related to an arbitrary deformation of space."

H. B. Phillips and C. L. E. Moore: "Algebra of plane projective geometry."

Anna L. Van Benschoten: "Products of quadratic inversions and linear transformations in space" (preliminary report).

Arthur Ranum: " N -dimensional spreads generated by ∞^1 flats."

O. E. Glenn: "Generalizations of a theorem on reducible quantics, due to Eisenstein."

F. R. Sharpe: "Finite groups of birational transformations in the plane."

John Eiesland: "On a flat spread-sphere geometry in an odd dimensional space."

C. N. Moore: "The summability of the double Fourier series, with applications."

S. E. Slocum: "A general formula for torsional deflection."

G. A. Miller: "Groups which contain a given number of operators whose orders are powers of the same prime."

R. G. D. Richardson: "Theorems of oscillation for three self-adjoint linear differential equations of the second order with three parameters."

L. A. Howland: "Points of undulation of algebraic curves."

C. N. Haskins: "Note on certain selective integrals."

L. P. Eisenhart: "Ruled surfaces with isotropic generators."

J. W. Young: "On algebras defined by groups of transformations."

J. W. Young: "A generalization to 3-space and to n -space of the inversion geometry in a plane" (preliminary communication).

L. L. Silverman: "On absolute or unconditional summability."

L. L. Silverman: "Tests for Cesàro summability."

W. B. Fite: "Note on a collineation group in n variables."

L. P. Eisenhart: "Congruences of minimal lines in a four-space."

The Chicago Section of the society met at the University of Chicago on December 29-30. The next meeting of the society will be held at Columbia University on February 24.

F. N. COLE,
Secretary

THE AMERICAN PHILOSOPHICAL ASSOCIATION

THE American Philosophical Association held its eleventh annual meeting at Harvard University, Cambridge, on December 27, 28 and 29, 1911. The meeting was marked by an unusually large attendance and by keen interest in the proceedings. A majority of the papers read centered around two main subjects selected for discussion, the one on the relation of object and consciousness in sense perception, the other on evolution. The discussion of the first subject was characterized by a departure from the method of previous meetings. This year both the papers read and the subsequent discussion were based on a carefully prepared committee report, in which both tentative definitions and an analysis of the problem were made. While this method did not result in an agreement of any great extent, it served to clarify the problem and to bring to a sharper focus the various issues involved in it. The committee which prepared this report was continued and given power to select the problem for next year, to formulate the issues involved in it, and to arrange for the discussion. Three papers and the presidential address were read on the subject of evolution, and these as well as the other papers read received vigorous discussion. The association empowered the executive committee to arrange, if possible, some future meetings with other societies in order that joint sessions may be held to dis-

cuss such questions as that of mechanism and vitalism.

E. G. SPAULDING,
Secretary

THE AMERICAN ASSOCIATION OF ECONOMIC ENTOMOLOGISTS

THE 24th annual meeting of the American Association of Economic Entomologists was held in the new National Museum, Washington, December 27-29. The meeting was called to order on Wednesday afternoon, December 27, and after the routine business of opening the session was disposed of the annual address entitled "The Relation of the Economic Entomologist to His Environment" was delivered by the president, F. L. Washburn, state entomologist of Minnesota.

On the following day papers were read at morning and afternoon sessions, and on Friday morning, at the close of several interesting papers, the final business of the session was transacted and the meeting adjourned.

The report of the secretary showed that the membership of the association had increased slightly during the year of 1911, and at the meeting over forty new members were admitted. This makes the total membership of the association, exclusive of foreign members, more than three hundred, and the interest shown in the association, especially by the younger members, augurs well for its future success.

Among the more important business matters that were transacted was an arrangement whereby the official organ of the association, the *Journal of Economic Entomology*, will, in the future, be published by the association instead of by the publishing company, as heretofore. The present editorial board will serve for the coming year, with the exception of the business manager of the *Journal*, Professor E. D. Sanderson, Morgantown, West Virginia, who voluntarily retired. The management of the *Journal* has been placed in the hands of the secretary of the association.

The following officers were elected:

President—W. D. Hunter, Dallas, Texas.

First Vice-president—T. J. Headlee, Manhattan, Kansas.

Second Vice-president—R. A. Cooley, Bozeman, Montana.

Secretary—A. F. Burgess, Melrose Highlands, Mass.

A full account of the business transacted at the meeting together with the papers read with the discussions will be published in the *Journal of Economic Entomology*, the first number of which for the current year will be issued February 15.

At the present day, it seldom happens that due credit is not given to each chemist for any new facts which he may add to the sum of chemical knowledge and, conversely, it is usually an easy matter to attach to any given fact the name of the investigator who first discovered it. For reasons which, in part, at least, are obvious, these conditions are not always so easy to fulfil in the case of the fathers of the science. It is certain, at all events, that frequently recognition has here been long delayed and, even where the most fundamental facts are concerned, the determination of the parentage has had repeatedly to be revised.

At the very start, there is difficulty in settling what constitutes *discovery*. Scheele's preparation of oxygen undoubtedly took place a year or two before Priestley's, but his publication of the results was delayed until three years after Priestley's, and priority in discovery is generally held to require priority in publication.

Again, Paracelsus obtained what is now known as hydrogen by the action of iron filings upon vinegar, but Cavendish defined the substance by its properties, and so the discovery dates from 1766. Liebig prepared bromine, but set the sample aside, believing it to be a chloride of iodine, and Balard, who prepared the substance later, and recognized it to be a new halogen, became the discoverer. Similarly, a

MSS. intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹ Presidential address, delivered before the American Chemical Society at Washington, December 28, 1911.

hundred years before Priestley's time, Borch (1678) prepared what is now known as oxygen in large quantities by heating saltpeter, but he failed to ascertain any of its properties; and again, forty-five years before Priestley's experiment, Hales collected the gas from the same source over water (the first record of any attempt to collect a gas in this way) and obtained, by measurement, 97 per cent. of the theoretical amount. But Priestley, on August 1, 1774, liberated it from mercuric oxide. A lighted candle happened to be standing before him at the moment. By pure chance, as he himself says, and without any particular reason which he could afterwards recall, he immersed the candle in the gas and found that the combustion was unusually brilliant! He thus ascertained one distinct property of the substance and became the discoverer of oxygen. True, he thought at first that it was a compound of nitrous acid, earth and phlogiston, and only in the light of the views of Lavoisier and others, and after long delay, did he accept in 1786 the conclusion that it was an elementary substance. It may be noted that, although Scheele was a better experimenter, his idea of the nature of oxygen was not much clearer. He thought that fire-air (oxygen) united with phlogiston to give heat, and that the last was a compound of the first two. Evidently, in those days, isolating the substance, and defining one or two of its properties, together conferred discoverer's rights, no matter how grotesquely the nature of the substance was misunderstood.

I say "in those days," for Curie made several compounds of radium, establishing their relations to one another, and is justly held to be the "discoverer of radium," although no isolation of the element was attempted. Now that the science has developed, isolation can be dispensed with,

and, in point of fact, was omitted in most of the exploratory work amongst the rare metals. If this principle could have been applicable in earlier days, several of the decisions of chemical history might have been reversed. A hundred years before Priestley's time, Mayow (1669) had shown by conclusive experiments that atmospheric air was made up of two components, of which the active one formed twenty-five per cent. of the whole. In measuring the amount, he employed the same reaction subsequently used by Priestley, namely, removal of the oxygen by the introduction of nitric oxide and absorption of the product in water. But whereas Priestley was thereby estimating the "goodness" of the air, and had no idea that he was dealing with a mixture, Mayow was perfectly clear as to the interpretation of the results. The latter demonstrated that the same component was removed in combustion, by rusting metals, by the alcohol in vinegar-making and by the blood in respiration. He traced the animal heat of the body to a process analogous to that which heated the mass when marcasite rusted in the air. He identified this active component of the air as a constituent of saltpeter, and particularly of the acid part of this substance, and (like Lavoisier more than a century later) held that it was contained in all acids. Finally, he considered it to be an element, in the modern sense of the word. Unfortunately circumstances conspired to relegate to obscurity all his wonderful work and magnificently clear reasoning. Mayow was a young physician, and the divergent view-point of Boyle, as an older man and an eminent philosopher, received more attention. Again, the logical conclusiveness of Mayow's proof of the existence of oxygen as a distinct substance, was entirely over the heads of his contemporaries, and his way of thinking quite out of

harmony with theirs. In this point of view, he came a century and a half too soon. Such a proof, if offered at the present day, would be accepted as conclusive. The final isolation of the element would now be considered a matter of mere routine, that could be assigned to a beginner in research, as the basis of his dissertation for the degree of doctor of philosophy. Finally, the clouds of the phlogistic theory soon began to darken the sky of the science, and before long the spread of this remarkable notion, diligently fostered by Stahl, who had been born nine years before the appearance of Mayow's work, enveloped chemistry and the whole chemical world in an impenetrable fog. Since the believers in phlogiston started always with one absurd idea as the major premise, namely, that, in combustion and oxidation, some kind of matter *left* the burning or rusting material, the more rigorous the logic of the subsequent steps in the reasoning, the more certain was the attainment of uniformly false conclusions. The inveterate phlogistian, and everybody down to the time of Lavoisier, not excluding Priestley and Scheele, was forthwith an inveterate phlogistian, saw in simple, almost modern modes of thought, like those of Mayow, only the sheepest nonsense. If we all stood habitually upon our heads, naturally any one caught persisting in a tendency to view the universe in the normal way would be instantly adjudged insane. For these various reasons, Mayow's work was first neglected and then forgotten.

The story of Mayow suggests some additional conditions which determine the recognition of a discoverer, and the acceptance of his discovery. How often in the history of science has a dominating but conservative personality diverted attention from younger or less prominent men, or at the least, by hostile criticism, delayed the

acceptance of their ideas. The discoverer who occupies a conspicuous social position is, often, more readily detected. Then again, for the dealing of strict justice, the consequences may be almost as unfortunate when the discoverer is a century ahead of his time, like Mayow, as when he is three years late, like Scheele. And, finally, an intellectual plague like the phlogistic theory may be epidemic. An infection runs until a milder generation of the infecting organism is gradually evolved, or until the presence of the organism results in physiological changes which automatically give rise to substances that destroy it. Lavoisier was fortunate in arriving upon the scene when the disease was ready to loosen its hold. It was not that his fundamental experiments, upon the subject of air and oxygen, were new—the same conclusions could have been reached by putting together the work of his predecessors and contemporaries. It was largely because of his personality, and because he arrived at the psychological moment.

I have prefaced my address in this way, in order to furnish a setting for its subject. He lived from 1711 to 1765. He thus was educated, did his life-work, and died in the most virulent period of the phlogistic epidemic. Heat, light and weight were then forms of matter, yet, when he notices them at all, he combats these views, and makes experiments to disprove them. In a day when the jargon of the phlogistian was the only language of polite intercourse amongst chemists, he speaks and writes the language of modern chemistry—of the most modern chemistry. for he was a physical chemist. Needless to say, he lived at a time far removed from the psychological moment for a man holding such a viewpoint. Naturally, credit for his discoveries, and they were many, has all been distributed amongst others. It is quite

likely that some of you have never happened to hear his name—the name of Michael Wassiliewitsch Lomonosoff.

Even in Russia, although his work in literary and linguistic lines, his success as a man of affairs and his investigations as a geographer and a meteorologist had won for him enduring fame, the fact that he was primarily a chemist had been completely forgotten. It was Menshutkin² who, a few years ago, rediscovered him as a chemist, reprinted in Russian his scattered memoirs and collected all that could be found of his manuscripts, letters and laboratory note-books.

Although trained—chiefly in Germany—by, and along with, men who ardently supported the current views, he seems with astonishing ease to have thrown off the prejudices of his contemporaries, and to have achieved a perfectly independent view-point of his own. At that time, the emission of light-matter explained the phenomena of light. Largely through the enormous influence of Newton's selection of the emission theory in preference to the wave theory (first developed by Huygens in 1690), this remained the accepted explanation until after a hard struggle against the influence of Laplace (1817) and others, who were unconvinced, with the explanation of the phenomenon of polarization by Fresnel, the ether-wave theory finally triumphed. But Lomonosoff discusses (1753–56) the possible motions of ether—progressive, rotatory and wave-like—identifies the last as the basis of light, and goes in great detail into the nature of ether, and the properties of light-waves and the mode of their propagation.

In Lomonosoff's day, heat was also a

form of matter. The classical experiment of Rumford was made (1798) thirty years after his death. But, so strong was the prejudice, that, even then, the proof (by quantitative experiments) that heat could be generated without limit from friction, under conditions such that the addition of any substance or form of matter was impossible, did not carry conviction. Lavoisier believed (with some hesitation, it is true) in an imponderable *matière de chaleur*. It was not until after the work of Mayer (1842), who was at first persecuted for his views, and especially after the demonstration by Joule (1855–60) that heat and work were mutually and quantitatively inter-convertible, that the theory that heat was matter finally disappeared. Yet Lomonosoff, more than a century earlier (1744–47), in a paper on "The causes of Heat and Cold," discusses in detail the experimental evidence that motion is a source of heat, and that molecular motions are caused by heating. Radiant heat, of which then little was known, was transmitted by motions of the ether, which he believed to be of the rotatory variety. In all his papers, heat is always a mode of molecular motion. The paper named was the subject of vigorous discussion, particularly in Germany, and, after the views contained in it had been sufficiently abused, they were consigned to oblivion.

The kinetic-molecular theory of gases used to be attributed to Krönig (1856) and Clausius (1857). But Lord Rayleigh discovered in the archives of the Royal Society a very complete form of it, contributed by Waterston in 1845. The state of public opinion among physicists, even then, a century after Lomonosoff's work, may be judged from the fact that the committee of the society considered the content of the paper to be nonsensical, and refused to permit its public presentation. Lomo-

² "M. W. Lomonosoff, as a Physical Chemist," St. Petersburg, 1904. See also an article by Menshutkin, *Annalen der Naturphilosophie*, 4, 203.

nossoff's paper, read before the Academy of St. Petersburg in 1744, nearly suffered the same fate, for it was withheld from publication for three years. Starting with the view of Daniel Bernoulli (1738), to the effect that the pressure of gases was due to the impacts of their particles, Lomonosoff proceeded to develop ideas very much like those now held. According to him, for example, a rise in temperature caused increased motion of the particles, and resulted therefore in increased pressure. His theory differs from ours mainly in the fact that rotatory motions played a large part, and that the molecules had rough surfaces. Incidentally he points out that there is no limit to the possible amount of motion, and therefore no maximum of temperature, but that there is a minimum of motion, when the latter becomes zero, and there must therefore be a minimum of temperature. In a later paper (1750) he proves by his hypothesis that the pressure *should* be, as it was then known to be, inversely proportional to the volume. And he goes further, for, with surprising insight, he shows that, with increasing pressure, this relation will no longer hold, since the volumes of the particles themselves are not diminished. The reputed discoverer of this consequence of the theory is Dupré (who was thus anticipated by 115 years), and in 1873 Van der Waals finally put the same fact into definite form.

In all this, it must not be supposed that Lomonosoff was simply a reasoner, much less a speculator. The discussion is loaded with a wealth of experimental facts, many of them ascertained by himself. It is especially noteworthy, also, that his experiments, almost without exception, were quantitative. When we remember that the balance is a stubborn instrument, and that its evidence always went contrary to the conclusions of those who pinned their faith

to heat-matter and phlogiston, we perceive how completely his habits of work and attitude of mind were out of harmony with those of his contemporaries, and how startlingly independent were his modern ways of experimenting and reasoning.

Before turning to the part of his work that was more especially of a chemical and physico-chemical nature, a few words about his career may be of interest. He was born of peasant parents—Russian peasant parents of the early eighteenth century—about the year 1711, and in a village forty-five miles from Archangel. Opportunities for education there were none. Finally, at the age of nineteen, he reversed the procedure of the typical boy, and ran away, to go to school. At 24, he left the school in Moscow to attend the lectures of the professors in the Academy of Sciences in St. Petersburg. At twenty-five he was sent on a traveling scholarship to Marburg, where he studied chemistry under Wolff. After three years, he went to Freiberg, and two years later he returned to St. Petersburg. In both places, when he moved, the academy had to pay the debts that he had incurred! Upon his return home, he became adjunct professor at a salary of \$900, but the academy, being poor in money, paid its professors largely by gifts of copies of its publications, a sort of product for which there is an almost infinitesimally slow market. A year later, we find him in the university, lecturing in Latin on chemistry, geography and the Russian language. Lecturing in Latin upon the Russian language to Russian students! Such simple, blind devotion to a tradition surprises us—even when it occurs in a university. His active experimental work as a chemist began in 1744, when he was thirty-three years of age, and in 1845 he was appointed to the professorship of chemistry.

After three years of planning, a chemical laboratory was built, and on the 12th of October, 1748, it was opened. The building, a modest one, measured 45×36 feet, and was divided into a large room for work and two small rooms for lectures and storage. It cost \$4,000, and about \$1,800 additional was spent on furnaces and other equipment. Thus, in providing a place for laboratory instruction, as well as for research in chemistry, Lomonosoff was fifty years ahead of Hope in Glasgow and seventy-five years ahead of Liebig.

Lomonosoff's period of greatest chemical activity was compressed into the nine years that followed the opening of the laboratory, for in 1757 he resigned his chair. During the remaining eight years of his life the numerous activities of a public man, and a diversion of his interests into other scientific lines, interfered with chemical work.

Up to the end of the eighteenth century, there was utter confusion of thought in regard to the composition of materials. In considering the make-up of a specimen, and the changes occurring during an experiment, heat-matter, light-matter and weight-matter, as well as phlogiston, were taken into account. As we have seen, even Scheele interpreted the phenomena he observed upon the theory that heat was an oxide of phlogiston! The composition was often stated in terms of salt, sulphur and mercury, whether there was evidence of their presence or not. The "elements" of Aristotle, and cognate ideas, were used in describing and in thinking about chemical phenomena. In consequence, Priestley thought he had a method of measuring the "goodness" of air—as a quality—when in point of fact he was measuring the amount of oxygen—as a component. With the basal conceptions thus in a state of utter chaos, it is no wonder that the simplest

chemical situations were wholly misunderstood, and that the simplest experimental results, being described in terms of non-existent entities, and thought of in terms of non-existent relations, failed of their object. It was Lavoisier who received the credit for setting our ideas permanently in order, by his emphasis upon the significance of the evidence of the balance, and by his setting forth clearly the idea of chemical compounds and their component elementary substances, and by giving a classified list of the latter.

The chemical reformation might have come half a century sooner, however, if Lomonosoff's papers had been more widely known. As we have seen, to him heat and light were not forms of matter and phlogiston had no existence. His forms of matter were the same as ours, and his ideas of chemical composition, what it included and what it excluded, the same as ours. In his "Elements of Mathematical Chemistry"⁸ (1741), and in a later paper "On the Imperceptible Physical Particles, which Compose Natural Materials, and in which is to be found a Sufficient Basis for the Specific Properties" (1742-43), he gives a singularly clear and minute discussion of the whole subject. He distinguishes between the attributes (weight, volume, etc.) of a body or specimen, and the specific properties which characterize a substance. In modern fashion, he defines the "imperceptible particles" or "corpuscles" (molecules), which are portions of a substance, and the "physical monads" or "elements" (atoms) which are not decomposed in chemical change. He draws clearly and in detail the distinction between simple and compound substances, the latter of which contains the "prin-

⁸This and parts of others of his papers are published, in German translation, in Ostwald's *Klassiker*, 178.

apia" (elementary forms of matter) in chemical combination. The explanations are in experimental, and not obscure, theoretical terms.

In the paper on "Heat and Cold" (1744-47) he refers to Boyle's experiment, in which lead was sealed up in a retort and heated, when the lead and calx, upon removal, were found to have increased in weight. According to Boyle, this result showed that the heat, which alone could enter through the glass, had weight. Lomonosoff, of course, will not accept this conclusion and points out that the increase in weight of metals when heated in air must be due to union with material from the air, just as their increase in weight when placed in the flame of burning sulphur is due to union with "acid" from the sulphur. Later, in 1756, he repeats Boyle's experiment, and finds that, until the retort is opened and air rushes in, no increase in weight is observable. He thus performed one of Lavoisier's most fundamental and convincing experiments eighteen years in advance, and interpreted it correctly. It is apparent that Lomonosoff's sound views were based upon many quantitative experiments on combustion, although the laboratory note-books containing the details have not yet been found.

But, if Lomonosoff anticipated Lavoisier in his work upon the chemical relations of the forms of matter, he went far beyond Lavoisier in his views in regard to the uses of mathematics and physics in chemistry, and, in this direction, anticipated many of the points of view of the later nineteenth century. Lomonosoff's unfinished treatise, "The Elements of Mathematical Chemistry" (1741), of which only a fragment survives, deals with a conception which, in all his writings, he never ceased to urge, namely, the value of mathematical methods in chemistry. Ten

years later, in an "Address on the Uses of Chemistry" (1751), he speaks as follows:

If chemistry unites to solid form the separated and scattered particles in a solution, and brings forth various formations, it must be that she relies upon the strictest and most highly developed Geometry. . . . If she changes solids into liquids and liquids into solids, and divides and unites them to give various substances, it must be that she seeks counsel of the most exact and ingenious Mechanics. If chemistry, by union of different substances, gives rise to different colors, she needs the help of the most profound Optics. . . . If the knowledge-seeking, tireless investigator [in response to this] will only survey her through geometry, measure her forces by mechanics, and consider her through the science of optics, he will probably reach his desired goal.

In this we seem to see at least an adumbration of chemical crystallography, and of chemical dynamics and statics. He continues:

Why have investigators had no success? I answer that for this a very skillful chemist is needed, who is at the same time a mathematician. Has not the recent development of the science been along the precise lines which he thus lays down?

Lomonosoff's applications of geometry in "De Nitro" (1749), a comprehensive study of saltpeter, will illustrate his own attempts to use mathematical methods. He discusses at length the crystalline form of the substance and proceeds to develop a theory of crystalline structure. In saltpeter, the prismatic form can be accounted for by an arrangement of round particles, in such a way that lines drawn through their centers always form equilateral triangles. In other substances, the arrangement is different, so that, for example, in common salt, the lines through the particles may form squares. As usual, he paid the penalty of being far ahead of his time. Yet he had anticipated by a century the essential conceptions of Bravais (1850), whose mathematical study of all

possible space nets, and their relation to existing crystalline forms, coming at a more favorable time, led almost immediately to the completion of development along this line by Sohneke (1867).

In the same address, he continues:

[The chemist] is surely unapt, who has made a mass of experiments, but, in the effort to secure quickly accessible products, hastens to the attainment of this as his sole goal; he overlooks those phenomena and changes occurring in his operations which might lead to the explanation of nature's secrets.

If this viewpoint, with its contempt for purely preparative chemistry, had been as prominent in the creed of all the chemists of the century and a half since Lomonosoff's time, as it was in his own, instead of being until recently the ideal of only a few scattered chemists, what a different science ours would have been. How many papers, signed by notable names, might have offered something of substantial scientific value, in place of a mass of new entries for the indexes of Beilstein and Dammer. In the preface to his treatise on saltpeter, he develops the same idea:

Since as yet no general physical bases for explaining the formation and composition of chemical substances exist, and since few physical experiments have been applied in chemistry so as to lead to the desired results, it may seem difficult, but we believe it to be possible, scientifically to describe the greater part of chemistry in terms of the interrelations of its own principles and their connections with those of physics. We do not doubt that, after the union of chemical with physical truths, we shall be able more successfully to understand the inner nature of substances.

Be it understood, these generalities are only summaries of the plans of study which, in his experimental work and in his papers, he attempts in thoroughgoing fashion to put into practise. Uttered as they were in the heart of the period of phlogiston, of heat-matter, and of confused experimentation and reasoning, they

have an uncanny sound, and almost terrify us with their supernatural prescience. How long have we had to await the psychological moment for the general application of these ideas! Had only the times been ripe; had only the atmosphere been healthy for the propagation of such ideas as his, instead of being virulently poisonous to them, our science might easily, by now, have been a hundred years ahead of its present position, and we might to-day have been listening to papers which, as it is, will not be read for a century. If Dante's *Divina Commedia* were to be revised by a chemist and brought up to date, the chief change he would make would be the provision of some horrible and revolting torment, calculated to give Stahl his just deserts.

The occasion is not a suitable one for going in detail into the mass of (for that time) novel and suggestive quantitative physico-chemical experiments which occupied Lomonosoff from 1752 to 1756. The extent of his plans—only partially fulfilled—may be judged from his "*Dromus ad veram chymiam physicam*" (Course in true Physical Chemistry, 1752), of which a considerable part was written, and much survives. In the introduction he mentions, amongst other aims of physical chemistry, this:

One must determine the specific properties of every substance as exactly as possible, in order that, after the composition has been ascertained by chemical operations, one may judge whether, and to what extent, each property is altered by changing a given constituent.

No statement of one of the purposes of physical chemistry could be clearer.

In the experimental part of the book, salt solutions receive much attention, and many modern problems may be recognized, such as measurement of exact solubilities at various temperatures, volume changes in solutions, capillary phenomena, action

of electricity upon solutions and relative deliquescent tendencies of salts. There is, of course, a good deal about crystallography. In the absence of the laboratory note-books, only parts of some of the tabulated results have been found. One set of experiments, chiefly with common salt, led to the conclusion that the freezing points of solutions are lower in proportion to the amount of the dissolved body. Even the most insignificant experiments were carried out quantitatively.

In Lomonosoff's laboratory, a good deal of special apparatus was devised. Measurements of the coefficient of expansion of air had been made, and a value (recalculated to 1° C.) of 0.003 (in place of 0.00367) was found. This led to the construction of an air-thermometer for measuring low temperatures. Incidentally, he reformed the Delisle scale of temperatures, which ran downwards from 0° at the boiling point of water to 150° at the freezing point, by simply inverting it (0° L. = 0° C., 150° L. = 100° C.). A thermostat for ice and water was employed in some experiments, and instruments for the study of oceanography, devised by him, came afterwards into general use. One of the most extensive pieces of work done in his laboratory was a study of colored glasses and mosaics, the results of which led to the establishment of a factory, still in successful operation, near St. Petersburg.

The achievements of Lomonosoff outside of chemistry were as remarkable as those within that science. He wrote a treatise on metallurgy, made investigations in meteorology and especially atmospheric electricity, in geology, and in mineralogy, and he assisted in the equipment of expeditions for geographical exploration. He observed the transit of Venus of 1761, and drew from his observations the

conclusion that the planet had an atmosphere "similar to, and perhaps greater than that of the earth," a discovery generally attributed to Schröter and Herschel (1791).

No undertaking that required courage and originality was outside the comprehensive sphere of his interests. He was the first to attempt to apply modern forms to the writing of poetry in the Russian language, and was the author of odes, poems, and even of tragedies to be performed in the Court Theater. He prepared a Russian grammar and a treatise on rhetoric. He devised a vocabulary for expressing scientific conceptions, and his terms are those now in use in Russia. As the most prominent Russian man of science of his time, public affairs claimed much of his strength. Taking him all in all, the rediscovery of Lomonosoff has added at once a chemist of the first magnitude and a personality of marvelous force and range to the limited gallery of the world's very greatest men.

ALEXANDER SMITH

COLUMBIA UNIVERSITY

*THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE
THE CAUSE OF HIGH PRICES¹*

IF the student of present-day affairs should classify the reasons for existing discontent, he would certainly give to the high cost of living a position in the front rank. Dominant political parties, ruling ministries, national policies and local conditions are indiscriminately blamed, yet the phenomenon of high prices is manifest among all progressive nations and in a degree throughout the whole world. It is in evidence in all countries regardless of tariff policy and monetary standards. It is also

¹ Address of the vice-president and chairman of Section I, Washington, 1911.

apparent under all forms of government. If there is any one class of countries in which the phenomenon attracts less attention it is in those which are least advanced in civilization. Obviously many of the causes to which this general rise in prices has been ascribed must be fallacious because of its universal prevalence.

In explaining the causes it is essential to recognize three fundamental facts, very obvious in their nature, but not so readily understood in their bearing upon the present situation:

1. The rapid progress made by leading nations in modern times.

2. The striking inequality of this progress in different branches of human endeavor.

3. The inevitable tendencies in every progressive era to overaction in enterprise and to extravagance and waste in expenditure.

The second and third facts are subordinate or incidental to the first and closely associated with each other. Let us explain the effect of each in its order.

1. Notwithstanding long periods of inertia and even of retrogression, the dominant note in the history of the race has been that of progress; this has been especially true in the last 100 years. Scientific progress has always been in the van, followed by material, intellectual and political progress. Science has given to mankind a constantly increasing control over nature. Inventions and discoveries have greatly multiplied the supply of useful articles adapted to satisfy human wants. As a result, the convenience and luxuries of one generation are regarded as necessities in the next. One marked effect of this progress is the alleviation of the struggle for existence, with the resulting leisure or opportunity to acquire greater skill and to discover new methods of production. The

requirement of less effort for obtaining the necessities of life gives a wider scope to human enterprise and makes it possible to multiply the achievements which contribute to the betterment of the race.

Nothing is more apparent than that the average per capita consumption is constantly increasing, not merely in essential food products, but in a variety of useful articles which are now available for more general use. Some tables prepared by the late Professor Richmond Mayo-Smith set forth clearly the increased consumption of divers articles in several countries of Europe in periods of 20 to 25 years:

ANNUAL CONSUMPTION PER CAPITA IN DIFFERENT COUNTRIES IN DIFFERENT YEARS

Article and country	Date	Date	Increase Per Cent.
Meat, France	25.9 kilos	33 kilos	27.41
	1868	1890	
Meat, England.....	100.5 kilos	124.5 kilos	23.88
	1871-75	1891-95	
Tea, Germany.....	.02 kilo	.05 kilo	150.00
Petroleum, Germany....	3.75 kilos	14.82 kilos	295.2
	1871	1896	
Flour, United Kingdom..	150 lbs.	257 lbs.	71.33
Tea, United Kingdom...	3.91 lbs.	5.77 lbs.	47.57
Eggs, United Kingdom..	12.6	40	217.46
Butter and margarine...	4.7 lbs.	11.1 lbs.	136.17
Cocoa23 lb.	.62 lb.	169.56
Bacon and ham.....	3.4 lbs.	15.9 lbs.	367.64
Refined sugar	5.28 lbs.	41.53 lbs.	686.55

It may be noted that modern means of communication, the ready transmission of news and the increasing scope of industrial and commercial operations have brought about a solidarity of interest among nations and rendered it easy to obtain by international trade useful articles even from the remotest parts of the earth. These same forces have promoted political progress, the assertion of popular rights and a greater equality of opportunity. One effect of this has been that wealth and the consequent increase of average consumption are no longer limited to a few.

The development of a more peaceful disposition among nations has caused a great increase in both production and consumption. Human effort has been less occupied with warfare and more with the development and utilization of the world's resources. All these factors make possible a rising standard of living which increases prices, unless there is equal progress in the various branches of production.

2. Progress, however, has been notably unequal in the different branches of endeavor which supply human wants. It is necessary to keep in mind the difference between a rise in the price of certain classes of products and a general rise in the price level, to which reference will be made later. There is a substantial distinction between these two phenomena. New methods in industry and commerce are revolutionizing the means for supplying human wants, but their effect is far more helpful in some categories of products than in others. Whether this be the result of natural conditions or limitations upon our knowledge is not pertinent to this inquiry. The fact is obvious. Throughout all periods, notwithstanding changes in fashion and taste, there has existed a demand amounting to a necessity for certain essential products, such as food, clothing and shelter. It is evident that science, working through inventions and improved methods, has not accomplished the same results in agriculture, especially in producing food supplies, as in manufacture. The revolution in industrial methods and in the utilization of capital in large scale operations has not been accompanied by equal progress on the farm. Very considerable progress has been made, it is true, in carrying agricultural products to the market and in preserving them for use, but these pertain to transportation and to the middleman rather than to the original producer. Accord-

ingly, as we should expect, the prices of farm products have risen much more rapidly than the prices of manufactured articles. In a very valuable report of the Chief of the Bureau of Statistics for the Department of Agriculture for the year 1910, a comparison is made between the increase in the prices of articles purchased by farmers during the ten years from 1899 to 1909 and the increase in the value per acre of that which the farmers sell. For the articles purchased the average increase was 12.1 per cent., while the average rate of increase in the value per acre of that which the farmer sells was 72.7 per cent., or six times as much. The comparison is made even more emphatic when it is noted that among the articles purchased by farmers flour and lard show maximum, or nearly maximum, increase in prices in response to the higher prices obtained for wheat and hogs. To this rise in the price of articles of food there is one general exception, namely, the price of tropical or semi-tropical products, most of which show a decrease for reasons which do not exist in the case of products of the temperate zone.

The rise in the prices of agricultural products in the temperate zones is well illustrated in the case of raw materials used in the manufacture of clothing. Until this present year the price of cotton had shown a steady increase. The price of middling cotton per pound in the year 1895 was 7.44 cents in the New York market; in 1903 it was 11.18 cents; in 1910, 15.11 cents, or twice as much as fifteen years before. The price of fine wool in the month of January, 1895—for most of which year there was no duty—was in the eastern markets $17\frac{1}{2}$ cents; in 1903, 30 cents, and in 1910, 36 cents. It may be added that cotton and woollen cloth in their various forms show a much less increase in

price than the raw products from which they are made.

The same general facts are true with relation to cereals and all other food products of the temperate zones. A cause additional to the lesser degree of assistance from invention may be found in the greater scarcity of land suitable for profitable cultivation and in our own country especially the early cultivation of fertile areas was conducted with too much regard for immediate returns and consequently little attention was paid to permanent productive quality. It is of course plain that farm products as well as all articles show an increased price by reason of the greater cost of wages and of most of the supplies which farmers must use. This, however, is common to all branches of production.

The unequal development in different lines of production has of late become especially noticeable in the case of precious metals. Formerly success or failure in gold or silver mining was largely a matter of chance. Now, however, as a result of the discoveries and improvements in engineering, and much more in chemistry, gold or silver mining has assumed the position of a settled industry in which calculations of the profitableness of treating certain ores or digging along a lode may be made with a fair degree of certainty. It may be added that improvements in production are unequal not only as regards different classes of useful articles, but also for different articles of substantially the same class. This is true of various lines of manufacture, hardly any two of which have been affected in the same degree. The manifest effect of this inequality in the ease or difficulty of production is a change in their relative value.

3. There is an inevitable tendency toward overaction, misdirected energy, waste and extravagance in every progressive era.

This tendency has its roots in the very characteristics of human nature itself. It is due in part to the measure of uncertainty which pertains to all business undertakings and in part to the ambitions and dispositions of men. Whenever a new process is invented for satisfying a human want or a new market is discovered, it is probable that the inviting prospect of gain will cause an undue amount of investment and effort in that new direction, which results in a loss of capital and an over-supply of certain articles. The tendency to waste and extravagance is even more marked in the utilization of new facilities or the purchase of articles which please the taste or fancy. It is a well-known fact that the desire for the automobile has caused many persons to invest in this new luxury who could not afford it. A new style of house, or equipage, or of dress, all of which are common in a time of increasing wealth often lead to the discarding of that which under less favorable circumstances would be regarded as sufficient and to the purchase of other articles in accordance with present-day tastes or fashions. Social ambitions and the desire for luxury tend in the same direction; extravagance grows as facilities and attractive articles multiply. Along with these factors is the desire for ease and luxury which accompanies the accumulation of wealth. This is but a result of the fact that pleasure is more attractive than pain; that enjoyment is preferred to effort, hence the number of the unemployed increases and the amount of effort made for satisfying human wants diminishes.

An important factor of the present situation affecting the high cost of living is the rapidly growing cost of government, national, state and municipal. In case the proceeds derived from taxation are applied to essential improvements naturally no

waste would accrue, but there are nevertheless substantial differences between public and private enterprise. The former is managed with a less degree of care and supervision. Given a certain object, the expense of securing it by public management is usually greater than under private control. There is a still more important factor. The aim and nature of public expenditures differ materially from private investments. The latter are made with a view to an adequate return, a profitable income on the amount expended; in many instances, the former look to objects of a less essential nature, sometimes to monuments of grandeur or of art, which do not subserve any immediate purpose of utility. Public activities are often undertaken for conserving health or maintaining more perfect order and have in view considerations of general welfare most commendable in their nature, but such as would not be initiated in expectation of immediate profit. Again, they oftentimes provide for new facilities on a scale which private enterprise would not attempt. To all these must be added—and especial attention is called to this—the enormous burden of military and naval armaments now amounting, in the more civilized nations, to two billions per year, an economic waste which imposes an almost unendurable burden upon the world's resources. Again in prosperous times a disposition to indulge in excess and unwise undertakings is constantly manifest both in public and private expenditures. So long as there are limitations upon our ability to forecast the future, this will be true. No more helpful consummation in commerce and industry could be wished than that which by careful weighing of future needs and probabilities could adjust present activity to future demand.

In this connection it must be stated that

the inequality of the supplies of raw material requisite for human needs is a prominent factor in the situation. The lumber supply of the United States, which at one time seemed abundant and even inexhaustible, in view of the great demand for buildings, furniture, implements, etc., has been diminished to such an extent as to threaten an early exhaustion. Perhaps the wisest policy would have suggested that the state limit the cutting of timber and require that new forests be planted. However that may be, the diminishing supply of timber in the face of unusual demand has caused a rapid increase in the price of products of the forest, the advance from 1900 to 1910 being the greatest of any single class. A comparison of the figures prepared by the Bureau of Commerce and Labor shows that between 1900 and 1910 the wholesale prices of wooden ware and furniture increased about 20 per cent., while the prices of window glass and grades of earthenware decreased nearly as much. For this divergence there is an evident explanation, namely, that the supply of timber is becoming more scanty while that of sand and clay and other materials for glass and earthenware is inexhaustible and readily available.

There have been numerous illustrations of the increase in prices in the history of progressive countries. According to Boeckh, in the time of Solon an ox in Athens cost 5 drachmas, or nearly 3 shillings, a sheep 1 drachma, a bushel and 3 gallons of corn 1 drachma. Two hundred years later the prices rose to five times and in many cases to ten or twenty times their former amount. The quantity of money was increased by the spoil obtained by successful military operations and by the development of mining in the islands of the Mediterranean, in Attica itself, and in Thrace and the island of Thesos. In

Rome it is more difficult to trace the changes in prices of food. Corn was sometimes exacted as a tribute from conquered countries and sold by the state at less than cost and occasionally given away. The increase of prices was particularly rapid after the concentration of the chief mining industry in the hands of the Roman government. Cattle increased in price as well as corn. About 400 B.C. sheep sold for 7 pence, 3 farthings. At the date of the Christian era the price was 25 shillings. After the Carthaginian wars the Romans acquired the valuable mines of their enemies in the western part of Africa, also in Sicily, Sardinia and the south of Spain. A few years later the mines of Greece and Asia Minor came into the possession of the Romans; still later the mines of Macedonia and Thrace. In their later conquest, special effort was made to acquire supplies of precious metal.

In the year 1581 a dialogue was printed, attributed to one "W. S.," probably William Smith, entitled "A Discourse of the Common Weal of this Realm of England." The participants in the dialogue are a knight or owner of land, supposed to be Mr. Thomas Hales, a doctor of divinity, who, as it is conjectured, was Bishop Hugh Latimer, a husbandman, a tenant farmer, a merchant, a mercer and a capper. An enterprising publisher in the year 1751 republished this dialogue and basing the authorship on the initials "W. S." assigned it to William Shakespeare, a manifest effort to obtain a greater sale by deceit. The real date of the dialogue as appears from more recent investigation was the year 1549. This document is exceedingly valuable for students who are considering the subject of high prices, for if we leave out the influence of the larger aggregations of capital, and the characteristic features of modern business, practically every rea-

son for a rise in prices is advanced in it. Each ascribed to the occupation of the other the responsibility for the existing situation. Views are expressed upon the benefits of protective tariffs against foreign products, upon the balance of trade, upon the exactions of the middleman, upon the increase in rents of agricultural land. One of the characters expresses the opinion that avarice is the cause of high prices. Another mentions the great increase in the cost of necessary articles. One of them says: "Within these 8 years you could buy the best pig or goose that I could lay my hands upon for 4 pence which now costs me 8 pence and a good capon for 3 pence or 4, a chicken for a penny, a hen for two which will now cost me double the money, and it is likewise of great ware as of mutton and of beef." It was maintained in this discussion that price determined rent and not rent price. The husbandman conceded that if he were commanded to sell his wheat and other products at the old price he would have enough to pay his landlord as in times past, but he says that he must buy iron, salt, tar and pitch, all of which brought a higher price than formerly. One cause of the increase of prices, which is pointed out in this dialogue, is the clipping of coin which caused the good coins to go abroad for use in foreign trade. There were, however, more universal causes than this. Bodin, a French political philosopher, of the last half of the sixteenth century, states as an undoubted fact that there had been a revolution in prices. He gives six reasons for it:

1. The great abundance of gold and silver which resulted in a decrease in its purchasing power. The discovery of America and the increase of commerce and the development of banks caused the great abundance.

2. The monopolies of the Guilds and of the tax farmers.

3. The ease with which wine and corn—the chief products of France at that time—might be exported, thus increasing the price at home.

4. The extravagance of the Court.

5. The general leisure in the community.

6. The debasement of money, a practise which was prevalent in France at that time.

Mr. Jacob, in his excellent work on "Precious Metals," ascribes the increase in prices, of which complaint was made in the dialogue referred to, to the increased production of the precious metals and traces with great research the coincidence between their increased supply and the high prices of that time. A similar object lesson in the history of prices is derived from a comparatively recent period. In the years from 1789 to 1809, the average price of commodities rose from an index figure of 85 to 157, or more than 80 per cent. There were many contributing causes, such as the prevalence of war and the interference with international trade caused by the French Revolution and the Napoleonic wars. Mr. Tooke lays stress upon the poor harvests of that period, but Professor Jevons ascribes the increase to the larger production of gold and of silver and points out that metals and oils were more affected than grain. Beginning in 1809, for a period of 40 years, prices fell from an index number, as measured by Professor Jevons, of 157 to 64 or nearly 60 per cent. This decrease has been very generally ascribed to the falling off in the production of precious metals which did not revive until the gold discoveries in California and Australia. There was a temporary rise after 1839, apparently due to the inflow of Russian gold following its discovery in Siberia in 1830. The great activity prior

to 1837 was also a contributing cause. It should be carefully borne in mind that this period from 1809 to 1849 was a time of great industrial advancement in which many inventions and improvements were utilized. In the period from 1849 to 1873, prices rose from 64 to 86, or about 33 per cent. The rise was interrupted by the crises of 1857 and 1866 and greatly accelerated by the exceptional activity prior to 1873 and was presumably due to the gold inflation following the development in 1849 in California and several years later in Australia. In the period from 1873 to 1896 prices fell in gold countries and this is ascribed to the decrease in the production of gold, to the adoption of the gold standard in the more advanced nations, thereby discontinuing the general use of one of the precious metals, at least as far as free coinage was concerned.

Manifestly there were other causes for the decrease in prices at this time. The great increase in facilities for transportation, culminating with the opening of the Suez Canal in 1869, brought different portions of the earth nearer to each other and made it possible to utilize the abundance afforded by outlying districts for the benefit of the more settled areas where food products were becoming less abundant. Again there were most notable increases in the mechanical arts. So considerable was this decrease in prices that several writers, of whom perhaps Mr. David A. Wells is the best example, came to the conclusion that the period of the most buoyant activity had come to an end; that thereafter the people would occupy themselves with repair and replacement or in utilizing discoveries already made. In other words, the most profitable production had reached a limit.

A very valuable contribution to the subject of prices is furnished by a comparison

between gold and silver standard countries. In India, where silver was still the money of the people, the index of prices rose from 107 in 1873 to 140 in 1896. In Japan it rose from 104 in 1873 to 133 in 1896, or a little less than 20 per cent., while in gold-using countries prices fell off more than 20 per cent. From 1896 to 1909 there has been a rise in prices contemporaneously with a great increase in the quantity of gold mined in South Africa and in different portions of the United States and Alaska.

Let us draw a little more fully the comparison between these eras of high and low prices and the production of gold. From 1789 to 1810, it has been stated that there was a rise in prices. During these years the average production of gold in the whole world was a little less than \$12,000,000 per year, and that of silver approximately \$37,000,000, or \$49,000,000 in all. Beginning in the year 1811 the annual average for the next ten years was \$7,606,000 of gold or a diminished supply of more than 33 per cent., and \$22,000,000 of silver, a diminished supply of about 40 per cent. In the following decade from 1821 to 1830 there was an increase in the mining of gold and a decrease in that of silver, but the total annual average was slightly less than from 1811 to 1820. From 1831 to 1840 there was a substantial increase in both metals amounting to about 33 per cent. From 1841 to 1850 gold production increased from about \$13,000,000 per year to \$36,000,000. However, in the forty years from 1811 to 1850, inclusive, an era of low prices, the average annual production of gold was barely \$17,000,000 per year; then with the opening of the mines in California and Australia the average suddenly rose from \$17,000,000 to over \$130,000,000, and to a still greater figure from 1856 to 1860. This was a period of

rapidly rising prices. After this there was somewhat of a decrease. The lowest annual production was for the four years, 1874, 1875, 1876 and 1883, in each of which the production was between ninety and a hundred millions. A practically uniform and very large increase commenced in the year 1891 with \$130,000,000, which increased to the enormous figure of \$236,000,000 in 1897, after which with slight interruptions resulting from the Boer war, the still higher figure of \$454,000,000 was reached in 1909. It thus appears that the production for the single year 1909 was more than two thirds as much as for the forty years from 1811 to 1850. It was greater than the combined coinage value of gold and silver for any year prior to 1898 and five times as great as the production of gold in the year 1874.

A further fact to be taken into account, of course, is the relation of the annual increment to the accumulated supply. Divers estimates of the world's stock of gold have been made. That which should be considered is the portion used for money in the form of coin or bars of bullion. At the present time the annual production is equal to at least three and perhaps four per cent. of the total existing monetary supply. Of the \$454,000,000 mined in 1909, it has been estimated that \$145,000,000 was utilized in the arts. It is probable that this is a large estimate, but in any event the primary money of the gold standard countries was increased by \$300,000,000 in the year 1909. Indeed, according to the very carefully prepared estimate of Dr. Roberts, the Director of the Mint, the amount of coinage for that year is given as \$313,000,000.

It is not by the mere addition of gold to the monetary supply that prices are raised. There is an even more important stimulus to activity in the fact that this money is

used as a basis of credit; that countries which heretofore have been without railroads and modern facilities are enabled to borrow for the construction of great railway lines and public works, the full benefit of which is often for a long time postponed. There is a marked increase in the demand for materials for this work. Labor is more constantly employed and at higher wages. The consuming power of the average human being is greatly increased. Speculation is rife and this tends to raise prices.

The connection between the increased supply of the precious metals and the general level of prices has been so marked and has appeared in so great a variety of countries and of periods as to preclude the possibility of mere coincidence. Of course certain modifying factors should be taken into account. The rise in prices after the beginning of the increase in the supply of gold or silver does not become manifest until some time has elapsed. This can be readily explained, because a substantial increase is necessary to modify the relation between the existing stock of the precious metals and the accretions.

Again, there has usually existed a concurrence of factors which make for increased activity and rising standards of living, on the one hand, and the increased supply of the precious metals, on the other. The development of gold mining on a large scale has followed closely after discoveries and inventions. This concurrence is such that while it would hardly be safe to generalize upon it, there is a strong presumption of a connection between the two. A somewhat similar cause of the rise of prices, by reason of the increased supply of gold among the militant countries of the ancient world, may be traced in their activities to secure the control of mines from which the precious metals were obtained.

The foregoing facts emphasize the importance of the so-called quantitative theory of money in considering the question of prices. To give adequate treatment to this theory and to estimate the effect of the volume of money upon prices would prolong this paper to an undue length. It would manifestly be incorrect to state the relation of the volume of money in circulation to the general level of prices as a simple equation. The problem is much more difficult. On this subject Mr. John Stuart Mill wrote in his work on Political Economy:

The proposition respecting the dependence of general prices upon the quantity of money in circulation must be understood as applying only to a state of things in which money—that is, gold or silver—is the exclusive instrument of exchange, and actually passes from hand to hand at every purchase, credit in any of its shapes being unknown. When credit comes into play as a means of purchasing, distinct from money in hand, the connection between prices and the amount of the circulating medium is much less direct and intimate and such connection as does exist no longer admits of so simple a mode of expression.

Certain modifications are necessary in order to harmonize the quantitative theory with modern conditions. Only the amount of money actually in circulation can have any effect upon prices. That hoarded or out of circulation for other reasons can not exert any influence. On the one side, account must be taken of the variations in volume of transactions during periods of prosperity or depression and even at different seasons of the year. This factor affects the demand for the medium of exchange. On the other side, allowance must be made for the rapidity of circulation and the use of credit instruments which reinforce the monetary supply and thereby modify its influence upon the price level.

There are sundry current explanations of the present high prices which may be readily dismissed as untenable if advanced

as a reason for the general rise in the price level, however applicable they may be to the increase in the price of specific articles. What shall be said of the influence of the so-called trusts on prices? It is clear that complete monopoly or preponderant control of the market in the production or sale of any particular commodity affords opportunity to increase its price. The same result is apparent when separate producers maintain an agreement or understanding as to prices.

On the other hand, the superior economy and efficiency of large scale operations materially diminishes the cost of production and even more of distribution and should therefore tend to decrease prices. For this reason the concentration of industrial and commercial enterprise is a legitimate phase of business evolution. It must be said, however, with equal emphasis that thus far the general public has not experienced in reduced prices the benefit to which it is entitled because of the increased economy and efficiency resulting from great combinations. If the people do not receive their proper share of the benefits, strict control beginning with greater publicity and ending perhaps with the regulation of prices is the inevitable outcome. Certain it is that large scale operations have come to stay. If they can not be successfully regulated, it is probable that state ownership will be adopted in preference to a return to the old régime of smaller competing units.

In a majority of cases the statistics of prices do not bear out the assertion that the establishment of large corporations has always caused an exceptional increase in the cost to the consumer. In many instances, the higher prices are due in part at least to the greater expense of obtaining raw materials or to the increased labor and obsolescence charges to which all concerns

of whatever magnitude are alike subjected. In the table prepared by the statistician of the Department of Agriculture, to which reference has been made, it appears that among over eighty enumerated articles purchased by the farmer, there were only three, the cost of which diminished between the years 1899 and 1909. Two of these are comparatively unimportant, the third is coal oil, which fell off from 15.1 cents per gallon in 1899 to 14.2 cents in 1909. There were also substantial reductions in the prices of various forms of iron and steel in the same period, while, as already mentioned, those of practically all the agricultural products of the temperate zone increased.

The rise in the price level can not be ascribed to tariffs any more than to the trusts, though prices of particular articles may have been increased by them. In answer to those who maintain that the tariff is responsible for the high cost of living in the United States, attention may be called to the admitted fact that the rise in the price level has been universal under free trade, as well as under revenue and protective tariffs. In a single newspaper published at Paris last September, there were paragraphs giving accounts of meetings, some of which were attended by violence, in Berlin, Switzerland, Bohemia, Silesia and Galicia to protest against high prices. In other issues at about the same time there were paragraphs giving accounts of bread riots in France and of loud complaints against the high cost of living in England and Belgium.

It is a noticeable fact that many prices have risen in spite of reduced tariffs in our own country, as in the case of hides and shoes. In the whole list of increases in prices from 1899 to March, 1910, there is no more notable illustration than that of crude rubber, on which there is no duty.

The price rose from 80 cents in the former year to \$1.99½ in 1910. On the other hand, raisins and prunes, upon which there is a considerable duty, have shown a material fall, and sugar has not greatly increased in price except very recently, due it is claimed, to crop conditions. Instances might be indefinitely multiplied of the rise and fall of prices here and elsewhere irrespective of the duties levied. These illustrations show that the tariff is only one of the numerous causes affecting relative prices. It may often happen, as in the cases cited, that other causes so far outweigh the influence of the tariff that its effect can not be discerned.

As regards the cost of labor, while a high standard of wages is maintained in the United States and there have been notable increases in the wages of many classes of employees, it can not be said that there has been a disproportionate increase; the facts are quite the contrary because, generally speaking, the cost of living has more than kept pace with the increase in compensation.

As a rule, wages as well as retail prices do not immediately respond to changes as readily as wholesale prices or as rent and other items which make up the ordinary expenses of living. The basic fact which should be considered is the relative proportions of personal service and of improvements accomplished by inventions or labor-saving devices, in the production or distribution of any commodity. In cases in which machinery renders a more efficient service than formerly, the tendency is toward downward prices, but in case labor or personal service has been only partially aided by these improvements, or as in some cases not at all, the prices have increased.

Under modern systems of distribution the amount of personal service required is

relatively much greater than formerly and in this fact may be found a very important cause of high prices. Much more care is exercised in the preparation and handling of packages. Delivery is made to the consumer at his residence. There is no sufficient organization in distribution. As a result there is a vast amount of duplication. This service involves an exceptional cost as compared with the work of distributing large quantities. For example, the carrying of a ton of coal 150 miles to a city costs less than the transfer of that coal for a half or even a quarter of a mile to the home in which it is consumed. The cost of delivery of mail matter by carriers in cities and on rural free delivery routes is much in excess of the carriage in bulk by railway or steamship, even for very long distances.

Innumerable examples may be given of the very considerable difference between the original cost to the manufacturer and the final charge to the consumer. Some weeks since figures were carefully prepared in regard to the manufacture and sale of an article of clothing now in very general use. The manufacturer charged \$24.90 per dozen. Each dozen included different sizes. The retailer charged from \$4 to \$10 per garment. The total sales averaged about \$6.50 for each, or a total of \$78 to the consumer as against \$24.90 to the manufacturer. The retailer is not to be blamed. The pressure of population in cities, the greater demands of modern life resulting in higher rents and higher cost for services rendered to him, make it essential that he should charge more for the goods he sells.

An entire revolution in methods of distribution is imminent. The consumer will be brought nearer to the producer. Great warehouses will be substituted for small and scattered shops, especially in case of

staple articles where confidence in the seller or exceptional skill are not essential features. The possible economy of large-scale production and the undertaking by one organization of the various processes, even from the raw material through manufacture and distribution to the consumer, has been demonstrated by some of the great corporations of the country. However much we may decry this tendency, we may be reasonably certain that it will be adopted more and more in the future.

It would be rash to predict an early return to low prices. All the great factors which I have partially portrayed depend upon new conditions which have arisen, some of which are inseparably connected with substantial benefits to the human race. If prices have increased, human enjoyment has increased also.

That which is most noticeable in the consideration of this problem is the wide variation in the changing cost of divers commodities and facilities. After making due allowance, however, for this variation, there is a manifest increase in the general price level. Great economic laws will be potent in their effect upon these conditions. The enormous increase in the production of gold will be checked as this metal becomes less valuable in comparison with useful articles. Indeed, this fact is already forecast by the diminished annual increase in the years 1910 and 1911. The increasing price of farm products may stimulate a "back to the farm" movement, but whether this proves true or not it will undoubtedly encourage more scientific methods of cultivation and thus increase the average yield per acre. More intelligent and more adequate control will be exercised over great industrial and commercial organizations so that the benefit of modern developments in industry and

commerce may accrue in proper measure to all classes of consumers.

The same advances which have been made in production and in the distribution of great masses of commodities will, as far as possible, be applied to the minutest details of distribution. Our natural resources which have been wasted, or too largely absorbed by the few, will be more carefully utilized and every possible means be taken to preserve a proper share of them for the future. Thus in this present increase of prices as in all great economic changes there may be reasonable assurance that the ultimate effect will bring to all substantial benefit rather than harm.

T. E. BURTON

THE CENTENARY OF THE ACADEMY OF
NATURAL SCIENCES OF PHILADELPHIA

EARLY in the past year resolutions were adopted by the council of the Academy of Natural Sciences of Philadelphia approving of a fitting celebration of the centenary of the society on the nineteenth, twentieth and twenty-first of next March. The president appointed a committee of forty-one to make arrangements for such celebration.

The general committee, of which the president, Samuel G. Dixon, M.D., LL.D., is chairman, has been divided into sub-committees on printing and publications, meetings and addresses, invitations, finance and entertainment. In harmony with a preliminary report of this committee the publication of three volumes has been decided upon: A commemorative quarto volume of scientific memoirs, adequately illustrated; an index to the series of *Proceedings* and *Journal* up to and including 1910, now amounting to nearly one hundred volumes, and a detailed history of the academy by Dr. Nolan, of which the chapter contributed by him in 1908 to the "Founders' Week Memorial Volume" may be considered a prodromus. The last mentioned volume will be illustrated by portraits and views.

It has been decided to hold the first session on the meeting night of the academy, on

March 19, when delegates will be received and historical addresses will probably be delivered; two morning sessions will be devoted to the reading of scientific papers by members, correspondents and delegates; on the afternoon of the second day a microscopical exhibition will be given and the resources of the academy demonstrated; on the evening of that day a reception will be tendered by the president to members, guests and friends; and the proceedings will end with a banquet on the evening of March 21, the official birthday, of the academy.

The preparation of the proposed publications is progressing satisfactorily and the dignity and importance of the commemorative volume is assured. It is hoped that a united effort may be made to secure for the occasion a success commensurate with its importance in the history of the academy and in its relation to the advancement of science in America.

SCIENTIFIC NOTES AND NEWS

DR. FREDERIC A. LUCAS, director of the American Museum of Natural History, has been made a corresponding member of the Zoological Society of London.

DR. AUGUST WEISMANN, professor of zoology in the University of Freiburg, will retire in April.

DR. GEORGE B. SHATTUCK has retired from the active editorial management of the *Boston Medical and Surgical Journal* after a service of thirty-one years.

We learn from the *Journal* of the American Medical Association that Professor Theodor Ziehen, director of the psychiatric and neurologic clinic in Berlin, will resign his position at the end of the winter semester and discontinue all medical work, in order to devote himself exclusively to research in psychology. For this purpose, he will remove to Wiesbaden, where he will erect for himself a private psychological laboratory.

PROFESSOR ARMIN BALTZER, Berne, and Dr. Emmanuel de Margerie, Paris, have been elected foreign members and Professor Charles Depéret, Lyons, and Professor Arvid Gustaf

Högbom, Upsala, have been elected foreign correspondents of the Geological Society of London.

M. LECLAINCHE, professor in the veterinary school at Toulouse, has been elected a corresponding member of the Paris Academy of Sciences, in the section of agriculture.

At the ordinary scientific meeting of the London Chemical Society on December 21, 1911, it was announced that the council had awarded the Longstaff medal for 1912 to Dr. H. Brereton Baker, F.R.S.

At the dinner of the Western Society of Engineers, Chicago, on January 10, announcement was made of the award of the Octave Chanute Medal for 1910 in electrical engineering to Mr. H. B. Gear, general inspector of the Commonwealth Edison Company, Chicago, for his work on "devices for the distribution of electric light and power." Mr. C. P. Berg received the medal for mechanical engineering in the heat treatment of high-speed tools, and Mr. C. K. Mohler was awarded the medal in civil engineering for his studies of earth pressures.

THE Institution of Mining and Metallurgy of Great Britain has awarded gold medals as follows: Gold Medal of the Institution (two awards): (a) to Mr. E. P. Mathewson, M.Inst.M.M., general manager of the Anaconda Copper Company, Arizona, in recognition of his services in the advancement of metallurgy generally, and especially in regard to copper; (b) to Mr. Walter McDermott, M.Inst.M.M., in recognition of his services in the equipment of the Bessemer Laboratory of the Royal School of Mines and as the representative of the institution on the Board of Governors of the Imperial College of Science and Technology during the period of its establishment and organization; and to signalize his services in the advancement of metallurgical practise. The Consolidated Gold Fields of South Africa (Limited) Gold Medal to Mr. Walford R. Dowling, M.Inst.M.M., for his paper on "The Amalgamation of Gold in Banket Ore."

PROFESSOR H. W. RILEY, head of the de-

partment of farm mechanics of the College of Agriculture of Cornell University, was elected president of the American Association of Agricultural Engineers at the annual convention recently held at St. Paul, Minn.

At the meeting of the American Society of Bio-chemists, held in Baltimore, the following officers were elected: *president*, Dr. Archibald B. Macallum, University of Toronto; *secretary*, Dr. A. N. Richards, University of Pennsylvania; *treasurer*, Dr. Walter Jones, Johns Hopkins University; *councilors*, Drs. L. B. Mendel, Yale, and H. Gideon Wells, University of Chicago.

DR. EDWARD G. DEXTER, of Illinois, has been renominated by President Taft to be commissioner of education for Porto Rico.

MR. J. C. TH. UPHOF, of Amsterdam, author of "Die Pflanzengattungen," has been appointed gardener for the Botanical Garden at the Michigan Agricultural College. He will also do work in connection with the herbarium. He is expected to enter upon his duties in the latter part of February.

PROFESSOR THEODORE PFEIFFER, of Breslau, has declined a call to the directorship of the Agricultural Experiment Station, Möckern, near Leipzig.

MR. N. C. NELSON, instructor in anthropology in the University of California, has been appointed assistant curator in the department of anthropology, American Museum of Natural History. He will assume his duties next June and will give especial attention to North American archeology. Mr. George Borup, who was in charge of the third supporting party of Admiral Peary in his last polar expedition, has been appointed assistant curator in the department of geology and invertebrate paleontology.

DR. WEBER has been appointed director of the imperial health office, Berlin, to succeed Professor Uhlenhuth, who is at present director of the hygienic institute at Strasburg.

DR. ERWIN ERHARDT, of the University of Munich, is visiting the United States to study methods of treating cancer.

DR. L. A. BAUER has returned to Washing-

ton after a nine months' trip of inspection of the magnetic work being conducted, under the auspices of the Carnegie Institution of Washington, on board the *Carnegie* in the Indian and Pacific oceans and by land expeditions in Australia and Asia. *En route* he also visited the various magnetic institutions in the Pacific Islands, New Zealand, Australia, India, Burma, Java, China and Japan, and observed the total solar eclipse of April 28 at Tau Island of the Manua group.

The Auk states that Mr. Roy C. Andrews, assistant curator of mammalogy in the American Museum of Natural History, sailed for Korea on December 13. He expects to spend about two months at the whaling stations there, for the purpose of studying and securing specimens of the California gray whale and humpbacked whale. He then plans a trip into the mountains of northern Korea, known as Chokaku San, where about four months will be spent in collecting mammals and birds, if possible in regions not hitherto visited by zoologists.

MR. WALTER GRANGER, associate curator of fossil mammals in the American Museum of Natural History, is abroad engaged in part upon researches among the fossil mammals of the English and French museums, especially the old world relatives of the four-toed horse.

At the third lecture in a series on biological topics being given before Trinity College Frederic S. Lee, Dalton professor of physiology, College of Physicians and Surgeons, New York, exhibited, for the first time in this country, cinematograph films representing phases of muscular action, such as the reaction of the perfused heart to various agents, ciliary and flagellate motions in *Trypanosoma*, etc.

CAPTAIN H. G. LYONS, F.R.S., late director of the Egyptian Survey, will give a course of lectures before the Royal Geographical Society on February 9, 13 and 16 on the North African Desert.

A PORTRAIT of the late Dr. John Ashhurst, Jr., has been presented to the College of Physicians, Philadelphia.

DR. JEAN BAPTISTE EDUARD BORNET, the algologist, member of the Paris Academy of Sciences, has died at the age of eighty-two years.

THE death is announced of William Thynne Lynn, former assistant at the Royal Observatory at Greenwich, at the age of seventy-six years.

DR. JAN. KOWALEZYK, astronomer in the observatory at Warsaw, has died at the age of seventy-eight years.

M. ARTHUR DE CLAPARÈDE, the geographer, has died at Geneva, at the age of fifty-nine years.

THE sixth triennial congress of the International Association for Testing Materials will be held in the Engineering Societies building, New York, beginning on September 3, 1912.

A JOINT meeting of the British Institution of Mining and Metallurgy and the Canadian Mining Institute will be held at Toronto on March 6, and the following days.

THE *Bulletin* of the American Mathematical society states that a new journal, entitled the *Vector* has been established at Warsaw. It will be devoted to mathematical and physical science in general and especially to questions of method and pedagogy.

Nature states that the council of the London School of Tropical Medicine has decided to establish a journal in connection with the school. Three parts are to appear each year, and part I. has just been issued. Sir Patrick Manson writes a foreword; original papers are contributed by Drs. Bayon, Daniels, Hut-ton, Leiper, Minett and Wise; and surveys of recent literature on tropical medicine and reviews of books complete the matter.

UNIVERSITY AND EDUCATIONAL NEWS

THE will of the late Mrs. Emily Howe Hitchcock provides that the Hitchcock mansion and the estate of forty-five acres, valued at \$50,000, shall go to Dartmouth College. To the college is also left Mr. Hitchcock's Di Cesuela collection of Cyprus antiquities. To the Mary Hitchcock Memorial Hospital, con-

nected with Dartmouth, is left an endowment fund of \$20,000, and to the Howe Library of Hanover, occupying the ancestral home of Mrs. Hitchcock, an endowment of \$50,000. To the Pine Park Association, a society formed to preserve the natural beauties of the town, is bequeathed a large tract of woodland adjoining the Vale of Tempe.

THE Marquise Arconati Visconti has given 500,000 francs to the faculties of science and arts of the University of Paris.

DURING commencement week, June 23 to 27, inclusive, the University of Michigan will celebrate the seventy-fifth anniversary of its founding.

CIRCULARS of information concerning the Kahn foundation for the foreign travel of American teachers have been issued by the trustees of the foundation. Two fellows will be appointed for one year beginning July 1, 1912, with a stipend of \$3,000 and an additional \$300 for the purchase of books, souvenirs, photographs, etc. The applications for appointment should be made on a formal blank which may be obtained from the secretary of the foundation, Sub-station 84, New York City, and should be filed on or before March 1, 1912. The present holders of the fellowships are Professor J. H. T. McPherson, of the University of Georgia, and Professor Francis Daniels, of Wabash College. They both sailed from this country during the summer and will have completed their year's travel by about August 1, 1912. They are both planning to make a complete trip around the world.

THE course on "Water Analysis and Water Supply" at the Rensselaer Polytechnic Institute has been expanded so as to allow of a preliminary course being given on "plankton" where special attention is devoted to those growths which produce taste and smell in reservoir water. Upon the completion of the above water course, each student is required to spend two weeks at work on local municipal slow sand filter beds and also on filters of mechanical type whereby he acquires a practical knowledge of the workings of full-

sized city filter plants. The cities in the neighborhood of Troy supply good illustrations of the different modern methods of water purification.

THE *Bulletin* of the American Mathematical Society states that during the Easter vacation of 1912 an extensive course in mathematics and physics for advanced teachers will be held at Göttingen under the direction of Professor F. Klein.

DR. C. RANKIÄR has been appointed professor of botany, and director of the Botanical Gardens at Copenhagen.

DR. GILBERT T. MORGAN, assistant professor of chemistry at the Imperial College of Science and Technology, South Kensington, and junior hon. secretary of the Chemical Society, has been appointed to the chair of chemistry at the Royal College of Science, Dublin, vacant by the retirement of Sir Walter Noel Hartley, F.R.S.

DR. THEODOR BOVERI, professor of zoology at Würzburg, has been called to Freiburg.

DISCUSSION AND CORRESPONDENCE

NUMBER OF STUDENTS PER TEACHER

TO THE EDITOR OF SCIENCE: It appears to me that the only correct way to determine the average number of students handled per teacher in any school is to divide the number of student hours per week by the number of teacher hours per week.

For example, let there be 15 teachers and 300 students. This does not mean that on the average one teacher instructs 20 students in a recitation or class. Suppose each student takes 15 hours per week, and that each teacher instructs only 12 hours per week. There are therefore 15×12 classes per week for 300×15 students, since each student appears in 15 classes. The average number of students in each class is therefore

$$300 \times 15 \div 15 \times 12 = 25.$$

In general, therefore, the average number of students which each instructor has to handle in one recitation is the number of student hours divided by the number of teacher hours, in one week.

The average number of hours per week re-

quired of each student and each teacher, viz., the number of student-hours and teacher-hours per week divided respectively by the number of students and teachers, are also important numbers in respect to the average work required of students and teachers.

ARTHUR S. HATHAWAY

ROSE POLYTECHNIC INSTITUTE

FUNDULUS AND FRESH WATER

"*Fundulus* and Fresh Water" in your issue of December 29, 1911, recalls some experiences I have had with these fishes in transferring them from salt and brackish to fresh water. *Fundulus heteroclitus* may be so transferred more safely, the less degree of salinity there is in the water whence they were derived. Most of my specimens came from the Hackensack River and its creeks, varying from the saline Newark Bay to the almost entirely fresh water at Little Ferry and at the heads of the creeks. While very few of those transferred from salt water directly to fresh survived the sudden change, an increasing number survived of those gradually transferred in the course of a week or two, through a number of changes of water. My records show that such fishes lived from four to six months, up to two years; one lived over three years. I never succeeded, however, in making a successful transfer of the highly colored breeding males.

Fundulus diaphanus, though known almost entirely as a fresh water species, when taken from salt water also offers difficulties in transferring, thus showing that successful transfer in all cases appears to be a matter of very gradual accomplishment.

Fundulus majalis I never succeeded in transferring, no doubt because of its being a purely marine species.

Cyprinodon variegatus also can be gradually accustomed to a change of water, but being practically only an anadromous fish during breeding time does not very long survive.

It is possible that these cyprinodonts being great rovers can ill bear small quarters and this may be one reason for their shortlivedness in captivity, as compared with the quieter cyprinids for instance.

Transfers were never successfully made to "hard," that is, well water. I never used distilled water but simply rain or city tap water.

Experiments made with Sticklebacks.—*Gasterosteus aculeatus* and *pungilius* and *Apeltes quadracus* also bear transfer which may ordinarily be made quite suddenly and without great loss. I transferred back an *aculeatus* directly from fresh to salt water; it survived only a few days, but as it was a spent male (in the fresh water) this may not be considered a fair test.

Suddenly transferred fishes drop to the bottom of the tank and slowly move about after some time; this is due to the difference in density chiefly, but differences in the temperatures of the water also have this effect, though it is sooner overcome.

HOBOKEN, N. J.

SCIENTIFIC BOOKS

The Flora of Boulder, Colorado and Vicinity.
By FRANCIS POTTER DANIELS. Volume II., No. 2, University of Missouri Studies. Price, \$1.50.

The author of this excellent piece of work is not a professional botanist but a specialist in Romance languages. While engaged in teaching French in the summer session of the University of Colorado in 1906 he made the collections upon which the present report is based. Through the University of Missouri, with which institution Dr. Daniels was formerly connected, his book of over 300 large octavo pages has been issued as a number of the "University of Missouri Studies." It is sumptuously printed in large type with wide margins and generous spacing.

Dr. Daniels collected 1,036 species of plants during the single summer that he was in Boulder. To this number are added in his printed list some species reported from the vicinity in Rydberg's "Flora of Colorado" together with others from various sources. The total number listed seems to be about 1,240. At various points in the body of the list new species and varieties are described. It is unfortunate that because of lack of time Dr.

Daniels was unable to consult the university herbarium at Boulder. This collection, containing some 5,000 sheets of Boulder County specimens, is, therefore, not reported upon in the present publication. However, the large number of plants collected by the author himself must surely comprise a very considerable part of the flora. His list is bound to be of great use to students of the local flora.

In addition to the systematic list of species and localities there is a fifty-page introduction in which various ecological matters are discussed. This is evidently not written for the professional botanist for the language is popular, not to say "breezy." One is therefore just a bit surprised by such terms as *Ensiformes*, *Rimosæ*, etc., which, set in heavy bold-face type, stare uncompromisingly at the patient reader who may happen to be innocent of a knowledge of the classical languages.

A very full index completes this creditable publication.

FRANCIS RAMALEY

UNIVERSITY OF COLORADO,
BOULDER, COLO.

SCIENTIFIC JOURNALS AND ARTICLES

Terrestrial Magnetism and Atmospheric Electricity for September, 1911, contains the following articles:

"Magnetic Chart Errors and Secular Changes in the Indian Ocean," by L. A. Bauer and W. J. Peters.

"Comparisons of Magnetic Observatory Standards by the Carnegie Institution of Washington, No. II.," by J. A. Fleming.

"Data for Abruptly-beginning Magnetic Disturbances, 1906-1909, No. II.": Reports from Batavia-Buitenzorg; Zi-ka-wei and Lu-ka-pang; Kew; Mauritius; Eskdalemuir; Dehra Dun, Kodaikanal, Barrackpore and Toungoo; Tortosa; Samoa; Falmouth; De Bilt; Rud Skov; Pilar; and additional data for Potsdam; Agincourt; Porto Rico, Cheltenham, Baldwin, Sitka and Honolulu.

"Peculiar Magnetic Disturbances of December 28-31, 1908," by R. L. Faris.

"The Magnetic Character of the Year 1910," by G. van Dijk.

"Mean Values of the Magnetic Elements at Observatories," compiled by J. A. Fleming.

Articles in the December issue are:

"On the Magnetic Field of the Earth," by L. Steiner.

"The Physical Theory of the Earth's Magnetic and Electric Phenomena, No. IV.," by L. A. Bauer.

"Atmospheric Electricity Observations on the Second Cruise of the *Carnegie* from New York to Colombo," by E. Kidson.

"On the Normal Magnetic Elements at the Mauritius Magnetic Observatory," by L. A. Bauer.

**TREMATODE GENERIC NAMES PROPOSED
FOR THE "OFFICIAL LIST OF
ZOOLOGICAL NAMES"**

1. The International Commission on Medical Zoology, appointed by the Graz International Zoological Congress, has made its first report on the names of Trematode genera parasitic in man.

2. Four members, namely, Blanchard (Paris), Monticelli (Naples), Stiles (Washington) and Zschokke (Basel), unanimously agree that the following eleven names are from the present standpoint of systematic zoology and nomenclature, the correct names for the genera in question, and that the species cited as genotypes are the correct types according to the International Rules of Zoological Nomenclature.

Clonorchis Looss, 1907, Feb. 1, 147-152, type *sincensis*.

Dicrocoelium Dujardin, 1845a, 391, type *lanceatum* = *lanceolatum* (= ? *dendriticum* sub judice).

Fasciola Linnæus, 1758a, 644, 648-649, type *hepatica*.

Fasciolopsis Looss, 1899b, 557, 561, type *buskii* (seu *buski* teste Blanchard).

Gastrodiscus Leuckart in Cobbold, 1877c, 233-239, type *sonsinoi* (seu *sonsinoi* teste Blanchard).

Heterophyes Cobbold, 1866a, 6, type *egyptiaca* = *heterophyes*.

Metorchis Looss, 1899b, 564-566, type *albidus*.

Opisthorchis Blanchard, 1895f, 217, type *felineus*.

Paragonimus Braun, 1899g, 492, type *westermanii* (seu *westermani* teste Blanchard).

Pseudamphistomum Luehe, 1908, 428-436, type *truncatum*.

Watsonius Stiles & Goldberger, 1910, 212, type *watsoni*.

3. The following commissioners have not voted: Jaegerskioeld (Gothenburg), Looss (Cairo), Luehe (Koenigsberg), Pintner (Vienna) and Shipley (Cambridge).

4. Notice is hereby given that the undersigned will wait until July 1, 1912, for any zoologist to raise objection to any portion of this report, and that on that date all names to which valid objection is not raised will be forwarded to the International Commission on Zoological Nomenclature with the motion that these names be included in the "Official List of Zoological Names" provided for by the Graz Zoological Congress.

5. All correspondence on this subject should be addressed to

C. W. STILES,

Secretary International Commission
on Zoological Nomenclature

HYGIENIC LABORATORY,

WASHINGTON, D. C.,

SPECIAL ARTICLES

NOTES UPON CRONARTIUM RIBICOLA¹

A NUMBER of new points have been worked out in connection with this fungus during the past year. A coarse yellow mottling of pine needles and of the bark on the twigs and leader occurs rarely, but is very characteristic when it does occur. It seems to occur only in trees which have had the disease for more than one year. It has developed in the greenhouse upon plants which were known to be infected and has been found in one lot of trees set out in the field.

In 1910 an attempt was made by the speaker to pick out all the infected trees in a lot of 10,000 three-year-old white pines. The remainder were then planted out by state authorities in a large open field where every tree could be easily found the next year, and in a locality where *Ribes* were absent for a considerable distance. An examination the next summer showed a considerable number which had swellings of the bark, but none were found with fruiting bodies of the *Perider-*

¹ Presented before the American Phytopathological Society, December, 1911.

mium. This, together with other experience along similar lines, convinced the speaker that the best single inspection possible will not remove all infected trees from a diseased lot. There will be at least a few hold-over cases which will develop afterward. This makes repeated inspection absolutely necessary and such repeated inspections *very* soon cost more than the value of the entire lot of trees. In most cases it will be real economy to pull up the trees and burn them at once.

The speaker, in cooperation with the state authorities, discovered the disease for the first time in the states of New Jersey and Virginia in 1911. In the former case the entire lot was destroyed by the owner, while the action taken in the latter is not known. No fruiting bodies were found in Virginia, but the swollen stems were present in a few cases. During the past year the disease has been shipped to us by a French firm and inquiry showed that they raised their trees themselves.

The finding of the teleuto stage of the fungus affecting the stipule and bracts of a *Ribes* leaf in the greenhouse, is believed to practically prove that the fungus may sometimes attack the bud scales of dormant bushes and cuttings; this very probably explains the anomalous appearance of this fungus in this country upon *Ribes* at Geneva, N. Y., and possibly in Kansas.

The single German nursery of J. Heins's Sons has sent us over 95 per cent. of the total amount of diseased stock that has been found in this country, yet they say they have no disease in their nursery. Barely a month ago the writer received samples of their white pine stock, which had just been submitted to the superintendent of the New York State Forests by Heins's Sons, and one at least had visible swelling of the stem, which the writer is confident is caused by the blister rust. This shows that he was correct in his former suspicion that they do not know the field characters of this disease. Inoculations have been successfully made by the writer with spores from diseased white pine trees sent by J. Heins's Sons to Lake Clear Junction and Salamanca, New York, and to the states of New Jersey and Connecticut, upon *Ribes* in

the greenhouse. The shipments thus tested were made in 1908, 1909 and 1910.

Experience with greenhouse inoculations on *Ribes* shows that the teleuto stage develops only after the cool weather of autumn sets in: that is, the uredo stage flourishes through the summer, but the teleuto stage does not appear until cooler weather prevails. The experiments for two years agree in showing this peculiarity. Greenhouse inoculations have been made upon young *Pinus strobus* with teleutospores secured by inoculation on *Ribes americanum* with acidiospores borne upon imported trees of *Pinus strobus*. Inoculations thus made in November, 1910, are now beginning to give results. One each of the trees inoculated with wounds and without wounds is now showing slight swelling such as is so characteristic of the blister rust disease.

PERLEY SPAULDING

OFFICE OF FOREST PATHOLOGY,
BUREAU OF PLANT INDUSTRY,
U. S. DEPARTMENT OF AGRICULTURE

THE BOTANICAL SOCIETY OF AMERICA

THE annual meeting of the Botanical Society of America was held at the Business High School, Washington, D. C., December 27 to 29, 1911.

The following were elected officers for the ensuing years:

President—L. R. Jones, University of Wisconsin.

Vice-president—B. M. Duggar, Cornell University.

Secretary—G. T. Moore, Washington University.

Councilor—Wm. Trelease, Missouri Botanical Garden.

These, with Arthur Hollick, treasurer, and C. L. Shear and R. A. Harper, councilors, constitute the council for 1912.

The following associate members were elected to full membership: D. H. Campbell, Stanford University; M. L. Fernald, Harvard University; J. B. Overton, University of Wisconsin; P. H. Rolfs, Florida Experiment Station; P. A. Rydberg, New York Botanical Garden.

Botanists elected to associate membership were: I. W. Bailey, Harvard University; F. S. Collins, Malden, Mass.; C. W. Edgerton, Louisiana Experiment Station; J. H. Faul, University of Toronto; R. McM. Harper, University of Alabama; H. Hasselbring, Bureau of Plant Industry; C. E.

Lewis, Maine Experiment Station; F. Ramaley, University of Colorado; D. Reddick, Cornell University; Frances G. Smith, Smith College; A. Stewart, University of Wisconsin; H. N. Whitford, Bureau of Forestry, Manila; F. D. Wolf, Alabama Experiment Station.

The address of retiring President Erwin F. Smith on "Some Aspects of the Relationship of the Crown-gall Disease to Human Cancer" and the symposium on "Modern Aspects of Paleobotany," participated in by F. H. Knowlton, John M. Coulter, Edward C. Jeffrey and Arthur Hollick, will be published and distributed to the members of the society.

The dinner for all botanists was held Thursday night. Mr. David Fairchild was toastmaster and a number of botanists spoke briefly upon the particular aspect of work in which they were interested.

The smoker given by the members of the Washington Botanical Society to all visiting botanists, on Friday night, was largely attended and a most enjoyable affair.

Following are abstracts of papers presented at the symposium on "Modern Aspects of Paleobotany":

I. *The Relations of Paleobotany to Geology*: F. H. KNOWLTON.

The present paper emphasizes the fact that paleobotany, in common with all the other branches of paleontology, admits of subdivision into two lines or fields of study—the biological and the geological—depending upon the prominence given to the one or the other of these phases of the subject. As the biological side is to be handled by other contributors to this discussion, the present contribution is, naturally, confined to the geological aspects of the science. It is shown that fossil plants afford a series of stratigraphic marks, serving for the identification of geological horizons, that are unsurpassed in value by those afforded by any of the many other branches of paleontology; and nowhere in the world is this fact so thoroughly recognized and accepted as in North America. Objection is frequently made, especially by botanists, that impressions of plants, the form in which they are most utilized by geologists, are often of doubtful biologic value. In reply to this it is shown that while the paleobotanist uses his utmost endeavor correctly to fix the biologic status of the material he uses, it makes not the slightest difference to the stratigraphic geologist whether the fossils upon which he most

relies are correctly named, biologically, so long as their horizon is known and they are clearly defined and capable of recognition under any and all conditions. The various phases of this aspect of paleobotany are set forth in detail, especially in its general geological and economic applications. The value of paleobotany in the interpretation of geological climate is also treated at some length.

II. *The Relations of Paleobotany to Botany*.

1. *Phylogeny and Taxonomy*: JOHN M. COULTER.

It is impossible to disentangle morphology and phylogeny, for the largest motive in modern morphology is to construct phylogenies. An excessive amount of overlapping will be avoided in this paper by laying the emphasis upon the inferences to be drawn from morphological investigations as to probable lines of descent, rather than upon the morphological results themselves.

As a result of the recently developed paleobotanical connections, the phylogeny of the vascular groups can be made now a resultant of comparative structures and actual history. Many an old phylogeny, based upon the comparative structures of existing plants alone, has been contradicted by history, which, in the nature of things, must furnish the final check upon any proposed phylogeny.

The title of this paper includes the taxonomy, but in so far as this deals with great groups, defined or discovered, it is covered by the statements concerning phylogeny. So far as it deals with the recognition of individual forms, it is clear that paleobotany must learn to recognize the relationships of fossil plants, or there will be no reliable taxonomy or phylogeny. So long as paleobotany depended upon the form resemblances of detached organs, there could be no taxonomy in the real sense. It was merely a cataloguing of plant material. But when it learned to uncover structure, it began to establish a real taxonomy. The contributions of paleobotany to taxonomy, therefore, may be summed up in the statement that it has begun to extend our schemes of classification into the ancient floras; that this has resulted in a far truer view of the great groups than their expression in the present flora can possibly give; and that this makes a rational phylogeny possible.

Illustrations are given of the great changes of view, brought about by paleobotany, that have occurred during the last decade. The illustrations are taken from the Lycopodiales (*Lycopodium*, *Selaginella*, *Isoetes*), showing the present opinion

as to the relation between the paleozoic and the present representatives; from Equisetales, showing the recent development of knowledge in reference to the paleozoic forms; from Filicales, showing the disappearance of the paleozoic assemblage once called ferns, and the development of knowledge in reference to Paleo-Marattiaceæ and Priniofilices; and especially from Gymnosperms, showing the remarkable reconstruction of the phylogeny of that group.

The great problem of paleobotany to-day is the history of angiosperms. Having perfected a weapon in the attack upon gymnosperms, it remains for the paleobotanist who is a vascular anatomist to uncover the origin of our greatest group, with its comparatively brief history. The origin is probably recorded in the Mesozoic, and we wish to see the significant structures, and not guess at external form, and much less guess at purely hypothetical connections. To this great task paleobotany is turning. We have had the guesses; and I am confident that presently we will have the facts.

2. Morphology: EDWARD C. JEFFREY.

The often perfect condition of preservation of plant fossils and the comparatively unbroken series, which they present, from the remotest times to the present, has been of the greatest importance for the modern development of plant morphology. It is now clearly recognized that the doctrine of recapitulation, far from being solely exemplified by zoologic types, is much more clearly and certainly deducible from the historical and developmental study of plants, which in this as in so many other respects, show themselves more advantageous for evolutionary studies than animals. It is clear likewise from the studies of the past decade, or decade and a half, that external morphology, even that of the reproductive organs, is of comparatively slight importance in connection with the doctrine of descent or its practical application to the natural system. Applied to the internal structures, the doctrine of recapitulation has many and striking illustrations in plants living and extinct. The correlation of paleobotany with internal morphology has shown, moreover, that the investigation of reversions is a very profitable direction of scientific exploitation. In addition to exemplifying recapitulation and reversion, plants further present another law, which is for the most part not apparent in animals. It has been shown, namely, that of the separate organs of the plant, the stem is most progressive and that root and leaf

lag behind in evolutionary development. As a consequence it is often possible to discover the structures of a remote geologic past in the roots or leaves of plants now living. In the principles of the recapitulation, reversion and retention of ancestral characters, we have as it were the three fundamental R's of morphological science, by the aid of which we are now for the first time in the position to begin the construction of a natural system.

3. Ecology: ARTHUR HOLLICK.

Plant ecology is that branch of botany which comprises the study of the interrelations of plants and their relations to environment. As a distinct science it is practically a product of the present generation, and the term has only been recognized in common usage within the past twenty-five years or so.

The relation of paleobotany to botany, in connection with ecology, is mostly concerned with the problems of phytogeography. Paleobotany has supplied the explanations of many puzzling facts in regard to endemic floras; the occurrence of some genus or species only in certain widely separated regions of the earth, and the geographic isolation or limitation of others. Most of the phenomena of plant distribution in general at the present time would have no logical or adequate explanation but for the facts which have been revealed by the study of fossil plants and their distribution in the past.

Among the many striking instances in such connection may be mentioned the explanations which paleobotany has given in regard to the endemic floras of Australia and other regions; the distribution of such genera as *Nelumbo* and *Liriodendron*; and the geographic isolation of *Sequoia*, *Taxodium*, *Ginkgo* and other genera.

In tracing the facts of the ancestry, former distribution and extinction of species and genera paleobotany has demonstrated that there is no necessity for invoking the aid of inadequate and unsatisfactory theories of migration in recent times, or the origin of a genus, *de novo*, in two widely separated regions, in order to account for some of the puzzling phenomena of modern phytogeography.

Following are abstracts of the papers presented at the scientific sessions:

The Connective between Conidia of Penicillium:
CHARLES THOM, U. S. Department of Agriculture.

References to a "connective" (Brücke, Dis-

junktor, Zwischen-zelle) between the conidia in species of *Penicillium* are widely scattered through the literature. This was figured by Strasburger in "Zellbildung und Zelltheilung" (1879) and reappears in the latest discussion of the group by Westling (1911). The appearances described under these names are easily seen and commonly but by no means uniformly found in certain species. To discuss this the usual method of conidial formation must be briefly described. The spore-bearing cell (sterigma, basidium, conidiiferous cell) has a definite permanent length of fairly uniform diameter, then tapers into a tube of smaller diameter from which the conidia are abstracted. This fertile tube elongates rapidly during the growing period. The nucleus of the cell divides, one daughter nucleus migrates to the tip of the tube, a wall then cuts the new cell from the old. The newly formed conidium in every species so far carefully studied is cylindrical, and more or less quickly swells to assume the globose or elliptical form characteristic of the particular species. The cylindrical form is lost so quickly that many preparations will not show such conidia, especially where growth conditions are not especially favorable. Similarly the tube may be very short or 2 to 3 μ in length in the same preparation. As the conidia swell from the cylindrical to the elliptical or globose form the appearance described as a connective is obtained when the primary wall of the original tube fails to follow the change in form and leaves an open space between itself and the new walls of the adjacent conidia in the chain. This appearance is by no means uniform in any species examined, but admits of the same explanation in every case seen. Nuclei have been fixed and stained in but few of these forms.

Perennial Gametophytic and Sporophytic Generations in Puccinia obtegens (Lk.) Tul.: EDGAR W. OLIVE, South Dakota State College of Agriculture and Mechanic Arts.

This brachyform of rust, better known under the name of *P. suaveolens*, grows at Brookings on an European variety of Canada thistle. As described by Rostrup and others, it is said to possess two distinct generations: one resulting from a general infection throughout the whole plant, in which the characteristic, sweet-smelling pycnidia are shortly followed by large, confluent sori of uredospores, among which are later developed a few teleutospores; and, second, a strictly local infection, in which only uredo- and teleutospores are produced and borne in small, scattered sori.

Some preliminary cytological investigations of the so-called first generation show that both uninucleated gametophytic and binucleated sporophytic mycelia ramify together throughout the infected plants. The uninucleated mycelium produces the pycnidia; and is present also at the base of the uredo-sori. But the binucleated mycelium also invades the uredo-sori and these sporophytic hyphae alone apparently produce the uredospores, which therefore should be regarded as secondary in their nature. Primary uredospores, produced by sexual fusions, were not observed. Teleutospores also arose from the same sporophytic mycelium.

The general infection of the Canada thistle is therefore due to the growth of two generations: a mixture of gametophytic as well as sporophytic mycelia; and the evidence appears to show further that both uninucleate and binucleate mycelia winter-over together in this mingled state in the underground parts of the plant.

A Revision of the North American Species of Puccinia on Carex: FRANK D. KERN and MARY A. FITCH, Purdue University.

Although there has been an accumulation of considerable information concerning the North American sedge rusts most mycologists have regarded this group as especially difficult. This is perhaps due to the fact that the telia do not usually present diagnostic characters. In the separation of these species it has been necessary to look for other features, and, as has been the case in several other groups of the rusts, it has been found that the urediniospores have furnished especially good characters. The social connections as brought to light by cultures are also important. The presence of amphispores in some of these species and the splitting of other species into races lend biological interest to these studies. About twenty-five species of *Puccinia* on *Carex* can be recognized in North America, the majority being endemic. About three fifths of these have had their life-histories worked out.

Cultures of Uredineae in 1911: J. C. ARTHUR, Purdue University.

The thirteenth year of culture work with plant rusts gave an unusual number of failures, largely ascribable to the unseasonable hot weather. Of the 193 available collections with resting spores, mostly on grasses and sedges, only 37 germinated, as proved by about 700 drop-culture tests. Out of the small number 14 infections were obtained, with 143 sowings. In addition to these 17 infections

were obtained from freshly gathered material of *Gymnosporangium*, *Peridermium* and *Æcidium*, out of 91 sowings.

The most important results of the year were (1) finding an aecial host for *Gymnosporangium speciosum* outside of the families Malacæ and Rosacæ, i. e., on *Philadelphus*, belonging to the family Hydrangiaceæ, and (2) finding that both the *Uromyces* and *Puccinia* on *Distichlis spicata* produce indistinguishable aecia on the same aecial hosts. The latter result taken in connection with facts brought out in former culture work leads to the conclusion that in some cases at least forms placed in the two genera, *Uromyces* and *Puccinia*, are not worthy of generic difference, and scarcely entitled to specific difference. They more truly represent races, or possibly varieties, of one species, rather than two species belonging to two genera.

Plus and Minus Strains in an Ascomycete: C. W. EDGERTON, Louisiana Experiment Station.

A species of *Glomerella* collected on a petiole of a cottonwood leaf in Louisiana has been producing perithecia on culture media for nearly a year and a half. The original culture has been separated into two distinct strains, called Plus and Minus. The Plus strain develops mature perithecia in masses occasionally, these being identical with other species of *Glomerella*. The Minus strain develops the perithecia singly or in two's or three's over and in the medium, but these do not come to maturity except on certain media and then the asci are very ill-shaped. When the two strains are grown on the same plate, there is a boundary line, where they come in contact, of well-developed perithecia. There is a cross-fertilization between the two strains, as is shown by the fact that ascospores in the same perithecium develop both strains on culturing.

The Morphology of Zygorhynchus and its Relation to the Ascomycetes: GEO. F. ATKINSON, Cornell University.

In *Zygorhynchus* the fruiting hyphæ are aerial and arise from the submersed vegetative mycelium. The branching is sympodial, the first sporangium terminating the primary hypha, the system finally bearing several sporangia, the successive ones usually standing higher. The sporangial branches are often more or less spirally curved.

The branched gametophore is the morphological equivalent of the sporangiophore, and the sexual branches are morphologically equivalent to the sporangial branches, and arise according to the

same plan. The gametophores and sporangiophores are usually pure, but sometimes mixed.

The first antheridial branch is terminal, and subtended by the oogonial branch. The latter curves around, is often spirally twisted, and comes in contact with the former, usually touching it on the side. The end of the oogonial branch then enlarges into an oval body and is divided by two cross walls. The terminal pointed cell in contact with the antheridium is the homologue of the ascomycete trichogyne, and the subterminal cell is the egg. The "zygospore" wall eventually includes the two cells.

The sexual apparatus of *Zygorhynchus* is of the same type, and may be regarded as representing the ancestral form of the same, in *Monascus*, *Gymnoascus*, *Pyronema*, etc., and the gametophore may be regarded as representing the ancestral form of the Laboulbeniales. It does not seem necessary, therefore, to derive the ascomycete trichogyne from the Rhodophycæ.

Development and Fertilization in Olpidiopsis: J.

F. BARRETT, University of Illinois.

Three species of *Olpidiopsis* were included in this study: *O. Saprolegnia* Cornu, on *Saprolegnia*; *O. vezans* nov. sp., on *Saprolegnia*, and *O. luzurians* nov. sp., on *Aphanomyces*.

Zoospores biciliate with the cilia of equal length and attached at or near the anterior end of the elongated body. Zoospores possess two motile stages separated by a brief period of rest, suggesting a primitive type of diplanetism. Individuality of the zoospore, after penetrating the host, is maintained throughout its development. Little if any amoeboid movement.

Segmentation of the sporangial contents apparently simultaneous throughout. Zoospores on escaping contain vacuoles.

True sexuality probably exists, and takes place by the fusion of two sexually differentiated individuals and the subsequent passage of the protoplasm of the smaller, male, into the larger, female, cell. This is followed by a supposed fusion of nuclei.

Both sexual and asexual reproduction develop rather rapidly from a uthe gold and to a multinucleate condition. The ooswall which is likewise multinucleate.

External conditions play a determination of the sex in fact adds evidence, in many plants, that nutritive conditions.

in the formation of the external or

Nuclear division is mitotic with the nuclear spindle intranuclear.

Variations in Glomerella: C. L. SHEAR, U. S. Department of Agriculture.

The results are given of studies of various races, strains, varieties and species from forty-six different host plants. Variations in morphological characters of all kinds were observed. Great variations in physiological characters, such as virility, adaptability to various hosts and reaction to culture media, also occurred.

Numerous generations started from single ascospores and conidia were grown under the same conditions. Rather striking and sudden variations occurred in some of these cultures, also intergrading forms and variations appeared. The conidial generations showed greater variation than the ascospore generation. Most of the variations studied show no direct relation to the culture media or other conditions of environment. More or less distinct races or strains were found to occur on the same host. These strains maintained their principal characteristics in cultures as long as they were grown.

The Perfect Stage of the Rose Actinonema: F. A. WOLF, Alabama Experiment Station.

The fruit bodies of *Actinonema rosæ* are not pyrenidia as in the Sphaeropsidales, but acervuli as in the Melanconiales. Persoon, who described the genus *Actinonema* ("Mycol. Eur.," 1822) characterized it as having radiate, sterile, mycelial strands. Fries ("Summa veg. Scand.," 1849), whose characterizations Saccardo employs, describes the genus as having a fibrillose, radiating mycelium, a delicate perithecium and bilocular spores. The genus *Marsonia*, whose conidia are similar to *Actinonema*, has a subepidermal acervulus. The acervulus of *Actinonema rosæ* is subcuticular. The rose fungus evidently possesses the characters of neither a typical *Marsonia* nor of an *Actinonema*.

Leaves affected with the conidial stage, when wintered out-of-doors developed a microthyriaceous, poor star. The shield and spores are distinct. These perithecia though consist of a shield and an innate apothecium, they are not really separate in origin and open like the Microthyriaceae. The Microthyriaceae are superficial, with a well-developed structure only on spores; the rose fungus is not like *Asterella*, which borne elements and

is proposed. This study connects for the first time the conidial and ascospore stages of the organism causing the black spot of roses. The new name *Diplocarpon rosæ* is given to the fungus.

Infection Experiments with the Powdery Mildew of Wheat: GEORGE M. REED, University of Missouri.

Experiments have been made in which eighty different varieties, belonging to nine different species of *Triticum*, were inoculated with conidia of *Erysiphe graminis* DC occurring on wheat. By far the larger number of these varieties proved entirely susceptible to the fungus. Forty-eight varieties gave an infection of 100 per cent.; seventeen, an infection of 70 per cent. or higher; four, an infection of 50 to 70 per cent.; four, a low percentage of infection (4 to 27 per cent.); and seven proved practically immune to the mildew. In the case of some of the latter varieties an occasional partial infection was noted.

The seven immune varieties found belonged to two species (*Triticum dicoccum* and *Triticum vulgare*), five of these varieties belonging to the former and two to the latter species. The emmers, as a group, have proved to be quite free from infection, although some, as the Winter Emmer and Red Emmer were entirely susceptible. It was noted that in every case the varieties which proved to be highly resistant to infection are spring varieties.

No one of the nine species of *Triticum* tested proved to be entirely immune. In every case one or more varieties belonging to each of the species gave infection.

The Organization of the Hymenium of the Hymenomycetes: A. H. REGINALD BULLER, University of Manitoba.

The Nature and Proper Treatment of Lichens: BRUCE FINK, Miami University.

An outline of the discussion to appear in the second paper of the series on "The Nature and Classification of Lichens" now being published in *Mycologia*. A statement of the difficulties due to the traditions regarding lichens and the consequent inconsistent treatment of lichens by many botanists. A brief outline of the arguments for or against various ideas and hypotheses, especially those of de Bary, Schwendener, Reinke, Schneider, Peirce, Danilov, Elenkin, Famintzin, Bessey and Clements. A conclusion reached as to whether the lichen is a colony, a dual organism or a fungus. In conclusion, the fundamental problems regarding the proper treatment of lichens by morphologists,

taxonomists, physiologists and ecologists are discussed briefly.

The Deposition of Iron on the Mycelium of an Aquatic Fungus: GEORGE T. MOORE, Washington University.

An aquatic ascomycete having peculiar spine-bearing spores, which readily germinate, was described. The mycelium from the germinating spores soon becomes encrusted with iron in much the same way that the so-called "iron bacteria" are covered with a deposit of iron. The material was particularly favorable for demonstrating that the process of iron deposition was not a vital one, as has been supposed for the bacteria.

A New Wood-penetrating Alga: GEORGE T. MOORE, Washington University.

An unbranched filamentous alga, with affinities with the Cladophoraceae was found penetrating the cells of a yellow pine board, which had been submerged in an aquarium for several years. The germination of the akinetes and peculiar habit of growth was described.

The Structure and Development of the Colony in Gonium: R. A. HARPER, Columbia University.

The 16-celled colonies of *Gonium* are formed from the mother-cell by definite mosaic development and are thus in sharp contrast with the colonies of *Hydrodictyon* or *Dictyostelium*. The mother-cell divides by three successive bi-partitions, the successive planes of division cutting each other at right angles. Each cell of the daughter colony occupies the same position in relation to its sister cells as it had in the undivided protoplasm of the mother-cell. The plane of the first division is apparently determined within the cell. The different cells of a mother colony divide at all angles with the plane of the colony as a whole. The changes of position and form which the cells of the daughter colonies undergo as they grow to mature size are apparently determined entirely by relations of adhesion, surface tension, etc. Only qualities of the cells as such appear to be transmitted; the organization of the colony as a whole is only indirectly represented in the mother-cell.

Some Physiological Conditions in the Culture of Spirogyra: W. D. HOYT, Rutgers College.

A large part of the trouble commonly experienced in growing algae in the laboratory is probably due to the water used, since, in physiologically pure water, *Spirogyra* was kept in perfect condition for several months. The nutrient solutions of Sachs, Molisch, Knop and Crone were tried. The best growth was obtained in Crone's

solution containing from 0.05 per cent. to 0.1 per cent. of total salts.

As has been shown by others, tap water and ordinary distilled water were highly toxic. The contained toxic substances were partially or wholly counteracted or removed by the addition of some, but not all, absorbing substances; by a high concentration of nutrient salts—0.5 per cent. to 1 per cent. of total salts; or by great heat. The results obtained indicate that the toxic bodies of tap water and distilled water were different substances; that those of tap water were, in part, volatile organic substances; and that those of distilled water were largely non-volatile inorganic substances.

A good growth was obtained only when a properly balanced solution containing all the nutrient salts was used, but the salts of any two of these metals gave a better growth than the salt of any one metal when used alone. No specific antagonistic action was observed—a mixture of magnesium and potassium salts seemed just as favorable as a mixture of magnesium and calcium salts.

A colloidal solution of silver was fatal in all concentrations as low as 0.0000045 per cent. and was injurious in concentrations as low as 0.000000225 per cent. The addition to the weaker silver solutions of a 0.05 per cent. concentration of Crone's solution or of animal carbon produced marked improvement in the solutions. A colloidal solution of gold was only slightly injurious at a concentration of 0.009 per cent., while a colloidal solution of platinum of a .0096 per cent. concentration was not only not injurious during a short time, but produced improvement in tap water, in a weak colloidal silver solution, and in a solution of magnesium sulphate.

When filaments of *Spirogyra* were placed in colloidal gold or platinum, to which was added about 0.015 per cent. NaOH, the outer layers of their walls swelled and formed gelatinous-looking sheaths which often broke off in crumpled masses. These sheaths were not formed in either the platinum solution alone or in the NaOH solution alone, but were formed when both NaOH and either gold or platinum were present. These sheaths were deeply colored by the gold and platinum, while the layers of the wall which formed no sheaths remained uncolored.

The Effect of Light on the Liberation of the Eggs and Spores of Dictyota dichotoma: W. D. HOYT, Rutgers College.

As the eggs of *Dictyota dichotoma* approach maturity, two layers can be distinguished in the walls of the oogonia, of which the inner becomes very thick as the egg ripens. In the discharge of the egg, the outer wall is burst, while the inner, still enclosing the egg, is protruded and is soon dissolved, freeing the egg and allowing it to round up. The outer layer of the oogonium wall then appears as a ruptured, crumpled membrane.

The discharge of the tetraspores was not observed, but probably occurs by the same mechanism since the young, mature and empty walls of the tetraspore mother cells show the same appearances as those described for the eggs.

Both at Naples and at Beaufort, North Carolina, the discharge of eggs in the laboratory began very early in the morning, when daylight was just visible or even, at times, before the slightest trace of light was discernible. At Beaufort, the time when this discharge commenced varied in different summers, and in the latter part of any one summer, but was fairly constant for the earlier months of each summer. Both at Beaufort and at Naples, about 70-80 per cent. of the eggs liberated in any one day were discharged within the first half hour and about 80-90 per cent. were discharged within the first hour. At Beaufort about 70-80 per cent. of the entire crop of eggs were thus liberated within a single hour of one day of each month.

Attempts to alter the time of the discharge by subjecting the plant to various conditions of light and darkness were effective only as they affected the healthy condition of the plant. The attempt to induce liberation at other times of the day by exposure to various degrees of light, or to alternating darkness and light, was entirely without success. Discharge occurred as abundantly in dishes covered with red and with blue glass as in dishes covered with white glass.

The tetraspores were liberated throughout the day, although the majority were discharged before 7:00 A.M. Attempts to alter their rate of discharge by exposure to various conditions of light and darkness gave no marked result.

The experiments indicate that the light rays affect the liberation of eggs and spores by their effect on the well-being of the plants, rather than by acting as a direct stimulus to the discharge of these cells.

Alternation of Generations in certain Florideæ:

I. F. LEWIS, Randolph-Macon College.

Species of several genera of Florideæ have been cultivated during the past two summers at Woods Hole. By using the method employed by Hoyt with *Dictyota* it has been found possible to rear to maturity sporelings of known origin. In this way it has been shown that in *Griffithsia Borne-tiana* and in *Dasya elegans* tetraspores without exception gave rise to sexual plants, which in *Dasya* were mostly male, and in *Griffithsia* about half male and half female. In *Polysiphonia violacea* carpospores produced, also without exception, tetrasporic plants. Hundreds of cases were observed. The experiments cited may be regarded as proof of the assumption, on cytological grounds, that there is an alternation of sexual and asexual individuals in Florideæ producing both tetraspores and carpospores.

The Germination of the Spore of Nematium multidum: I. F. LEWIS, Randolph-Macon College.

After being shed, and attaching themselves to some hard substratum, the spores of *Nematium* remain without visible change save a slight increase in size for twelve to twenty-four hours. The center of the spore is occupied by the large chromatophore with its pyrenoid, the latter bearing a marked resemblance to a nucleus, but larger. The small nucleus lies to one side of the pyrenoid. The first sign of germination is the protrusion of a germ tube through the spore wall. Into this the pyrenoid passes, along with most of the protoplasm. The spore cavity is left nearly empty. The nucleus, lying at the base of the germ tube, divides in the manner described by Wolfe for the nuclei of vegetative cells. One of the resulting daughter nuclei passes into the germ tube, the other into the spore cavity, where it becomes closely appressed to the wall as a structureless mass. The number of chromosomes in the first and later divisions is probably 8. A cross wall separates the germ tube from the nearly empty spore body, the latter taking no further part in development and soon dissolving in the sea water. The germ tube continues to elongate, and its nucleus divides in the usual way. The pyrenoid divides at about the same time, and a second cross wall cuts the germ tube into two parts, each with nucleus, chromatophore and cytoplasm. The apical cell so formed grows in length and divides. Repetition of this process results in the formation of a monosiphonous filament.

Nuclear Division in Spirogyra setiformis: F. MC-ALLISTER.

The first indication of nuclear division is the accumulation of protoplasm at the poles of the nucleus. Later the nucleole loses its regular outline and stainable material seems to be given off from it into the nuclear cavity. No spirem seems to be formed from the reticulum. When the nucleole is nearly or wholly disintegrated, fibers from the polar region enter the nucleus and at the same time all the stainable material contracts to form the equatorial plate. This now separates into two parts, which move to the poles as dense homogeneous masses. Vacuoles appear and ultimately the stainable material is uniformly distributed through the daughter nucleus as pale blue-staining bodies. Red-staining bodies appear. The blue-staining bodies lose their distinctness and part of them, at least, form a homogeneous blue-staining ground substance in which the several red, nucleole-like bodies are imbedded. This mass rounds up to form the nucleole of the resting nucleus. During nucleole formation a delicate reticulum has appeared.

The Effect of Gymnosporangium upon the Transpiration and Photosynthesis of Apple Leaves:
HOWARD S. REED and J. S. COOLEY, Virginia Agricultural Experiment Station.

In connection with pathological studies, the authors made determinations upon water elimination and carbon-dioxide consumption of healthy and rusted apple leaves. The varieties of apple known as York Imperial and Ben Davis were used. Transpiration was measured on twigs on the trees and determined in grams per square centimeter per hour. An average of five tests on Ben Davis apple leaves showed that in rusted leaves the water elimination was 50 per cent. of that in healthy leaves on the same trees.

For determining the rate of photosynthesis Ganong's photosynthometers were used. Experiments were always run in duplicate, using healthy and diseased leaves. Results were expressed as cubic centimeters of CO_2 consumed per square centimeter per hour. The diseased leaves showed marked diminution in power to consume CO_2 .

A Study of Protoplasmic Movements in Fungi:
F. M. ANDREWS, Indiana University.

Very little work has been done on the subject of protoplasmic movements in fungi. This study was undertaken in Pfeffer's laboratory to ascertain if the few observations made were correct and to extend them.

The fungi used for this investigation were *Mucor stolonifer*, *M. mucedo* and *Phycomyces*

nitens. They were grown in various nutrient media such as a 4 per cent. solution of cane sugar; in gelatine (generally 10 per cent.), plum juice and others.

In making these investigations it was first attempted to determine the nature of the protoplasmic movements in the fungal filaments as they occur under ordinary conditions. Secondly it was desired to ascertain the effect of external conditions in the streaming movements such as temperature, food, transpiration, osmosis, light, injury, etc.

The most favorable temperature for growth is from 23 degrees to 26 degrees for the plants used. Below the optimum sudden rise in temperature of a few degrees results in movement if the protoplasm is still or an acceleration where slow movement is already present if all the other conditions are perfect.

In most cases those nutrient media containing sugar of sufficient strength produced an active growth and filaments having a large diameter which was necessary for favorable study. The gelatine and plum juice media also produced actively growing and wide filaments. In some other media, as where the sugar was entirely absent, only feeble narrow filaments were found.

In actively streaming specimens dry air caused acceleration for a time and then cessation of movement. On using moist air immediately after movement recommenced.

Streaming can also be produced in the filaments of these plants by placing a solution of sugar about the filament. Streaming then begins and continues according to the strength of the solution for some time. If after stoppage of the movement fresh water is added, the movement recommences.

Light, while not so noticeable as the other factors mentioned, causes a slight acceleration of movement of the protoplasm after the plant has been darkened for a considerable time.

Also injury, if not too severe, may cause movements to begin. All the conditions here mentioned have no effect unless the protoplasm is in a condition for streaming.

A Method for Preparing Stained Cells in Toto for the Study of Karyokinesis: ALBERT MANN, U. S. Department of Agriculture.

A Comparison of the Somatic and the Reduction Divisions in Carex aquatilis: A. B. STOUT, New York Botanical Garden.

In *Carex aquatilis* the chromosomes can be identified as individuals in the resting nuclei in

root tips, tapetum and sporogenous tissue and they can be traced as separate individuals throughout the whole process of somatic cell division. They also maintain a serial order in which the chromosomes appear as individual spheroidal masses with a relative place relationship. This is most clearly in evidence during the prophase.

In the prophase of the reduction division, on the other hand, the chromosomes appear at synapsis as an extremely thin double thread which in the thick spirem stage again appears single. This is in marked contrast to the somatic prophase where the chromosomes maintain a separate individuality which can be traced. In the preparation for the reduction division the substance is spun out and the chromosomes are so closely connected end to end that they can not be identified as individual units. It would appear that in this condition the opportunity is given for mutual influence and exchange of substance between homologous pairs.

After the reduction division occurs the three nuclei which lie at the apex of the wedge-shaped spore mother cell divide, making six nuclei which then die and become flattened out against the wall. The wall of the spore mother cell functions as the wall of the microspore.

In the resting nuclei of the microspores the chromosomes appear again as separate individuals.

Precarious Tests for Chemotropism of Roots: F. C. NEWCOMBE, University of Michigan.

There is probably no part of a plant so sensitive to so many external stimuli as the tip of the root. The root-tip will give tropic responses to gravitation, in many plants to light, to moisture, heat, chemicals, in many species to pressure, to wounds.

The author has found still another response—that to a water-imbibed body in a water-saturated atmosphere. A piece of wet filter paper or of unglazed porcelain attached to the sloping side of the root will call forth a negative curve even in a water-saturated atmosphere. This result may be due either to a disturbance of hydrostatic conditions within the cells of the root, or to the accumulation in the attached body of volatile excretions of the root. The possible excretions must be volatile; for repeated use on successive roots of the same bits of paper, without washing, leads to no greater response. Either of the two possibilities assumed above could be interpreted as effecting traumatropic curves.

This extreme sensitiveness of the root-tip shows

how precarious are the results of authors who think to test the chemotropism of roots by applying to the tip bits of paper imbibed with chemicals.

The Nature of the Absorption and Tolerance of Plants in Bogs: ALFRED DACHNOWSKI, Ohio State University.

The considerations of the quantitative nature of habitat factors, which are rightfully desired as a basis for a theory of physiologically arid habitats, do not, however, render more clearly the nature of the absorption of plants in bogs and the nature of their tolerance to toxic substances in peat soils. The physico-chemical effects of toxic bodies are in part these: they reduce the available water content, and they act in varying degree directly upon the roots of plants and their functions. Since there are (under field and laboratory conditions) no differences in the evaporating power of the air, in temperature, in greater intensity of light, in the gradient of osmotic concentrations and in the possible rate of movement of water through the soil; and since no morphological limitations in the absorption and in the conduction of water (in the agricultural plants used) enter into the problem, the phenomena of absorption and of resistance to desiccation deal, plainly, with considerations of the permeability of the absorbing protoplasmic membrane, its power of endurance and its ability to transform the injurious bodies into insoluble, impermeable compounds. A study of the behavior of different species of cultivated plants and especially a number of their varieties forces the assumption that changes of a cytoplasmic nature are particularly important under the conditions of growth.

The Permeability of Protoplasm to Ions and the Theory of Antagonism: W. J. V. OSTERHOUT, Harvard University.

Experiments were performed to test the electrical conductivity of living tissues in various solutions. The results show conclusively that a great variety of ions readily penetrate living cells and that antagonism between salts may be explained by the fact that they hinder or prevent each other from entering the protoplasm. The ions of NaCl readily penetrate the protoplasm, but the addition of a small quantity of CaCl₂ greatly hinders this penetration. Such salts as KCl, MgCl₂, CsCl, RbCl, LiCl, NH₄Cl, NaBr, NaI, NaNO₃, Na₂SO₄ and Na-acetate act in general like NaCl while BaCl₂ and SrCl₂ act like CaCl₂.

The mechanism of this action is not fully under-

stood, but it may be stated that CaCl_2 , BaCl_2 , and SrCl_2 bring about visible changes in the plasma membrane which are quite different from those produced by such salts as NaCl , and it is hoped that a further study of these visible changes may throw some light on this question.

Observations on Evaporation and Transpiration in Prairie and Forest: B. SHIMEK, Iowa State University.

In an effort to determine the differences between forest and prairie plants which would account for their distribution, observations were made on the transpiration of certain forest and prairie plants in their native habitats and in transposed habitats. To illustrate the plan and purpose of the work two sets of plants are taken. In one of these cases *Phryma leptostachya* L. from the forest and *Kuhnia eupatorioides* var. *corymbulosa* T. & G. from the prairie were compared, and in the other *Anemone virginiana* L. from the forest and *Verbena stricta* Vent. from the prairie were employed for the same purpose.

Two stations were selected on a ridge near Iowa City, one side of which is prairie and the other forest, one station being located in each. The plants, which were as nearly as possible equal in size and vigor, were cut and inserted into bottles of water, which were sealed. Two plants, one from the forest and one from the prairie, were placed at each station, and the loss of water was determined at two-hour intervals.

In addition to this, observations were made at each of the stations on evaporation, and the meteorological conditions affecting it. The latter observations showed substantially the same relative results for prairie and forest as those previously published by the writer.

The results may be briefly summarized as follows:

The *Phryma* in the forest lost 1.9 gram, while that on the prairie lost 4.65 grams. The latter transpired very actively until it began to wilt, and then transpiration declined very rapidly, the plant soon becoming dry and crisp. The *Phryma* in the woods scarcely showed signs of wilting.

The *Kuhnia* in the forest lost 7.16 grams and remained perfectly fresh. That on the prairie lost 11.13 grams, and was also fresh at the close of the experiment. The diminution in transpiration in the forest was probably due in part to diminished activity on account of less intense light.

The *Anemone* lost 3 grams in the woods and 4.89 grams on the prairie.

The *Verbena* lost 6.58 grams in the woods and 27.4 grams on the prairie, transpiration in the woods declining in mid-day, being greater at both extremes of the day. The decline on the prairie in both cases was uniformly quite rapid. The greatest transpiration occurred in all cases just before wilting began.

The general result shows that transpiration and evaporation are not coincident.

Shade as a Factor Influencing Evaporation: G. P. BURNS, University of Vermont.

There is a general belief among some ecologists that the evaporating power of the air is the most satisfactory summation of the atmospheric factors controlling plant distribution.

In forest nurseries it is the usual practise to grow young pine trees in beds covered with racks whose sides are either wood or heavy paper and whose top is covered with lath. Every other lath is nailed, the free lath being later removed to produce "half-shade."

During the summer a study of the condition in the seed-beds has been carried on. The results as shown by the Livingston atmometer are given below.

Numerous stations were established representing all of the conditions found in nursery practise and in the adjacent forest areas. The control station was located in the nursery in a very large wire cage. The average amounts of daily evaporation from the various stations were as follows: control 45 c.c.; full-shade 19 c.c.; half-shade with solid sides 20 c.c.; half-shade with wire sides 43 c.c.; pine woods 16 c.c. Of these amounts from 17 per cent. to 25 per cent. is lost during the twelve hours 6 P.M.-6 A.M., the remainder during the time between 6 A.M. and 6 P.M.

The data gathered seem to show that the shading of young trees is a matter of evaporation rather than a matter of light, as is generally stated in the literature. The final word, however, must be spoken as a result of experiment.

The Investigation of a Climatic Gradient: FOREST SHREVE, Carnegie Institution.

The Santa Catalina mountains, in southern Arizona, rise from the desert plain at 3,000 feet altitude to a height of 9,100 feet. The lower slopes are characterized by desert vegetation, the middle altitudes by chaparral, the higher by coniferous forest. The influence of slope-exposure is such as to make the vertical limits of these zones and their component plants about 1,000 feet higher on

south-facing than on north-facing slopes. Instrumentation has been carried on at six stations, separated by vertical intervals of 1,000 feet. The data have furnished curves showing the altitudinal change of temperature, rainfall, soil moisture, humidity, evaporation and soil temperature. Mensuration has been carried on to determine the density and volume of the stands of characteristic trees at the different altitudes. Ratios of soil moisture to evaporation have been worked out from the instrumental data, showing the conditions which control the water intake and water loss of plants to be nine times as severe at 3,000 feet as at 8,000. The duration of the most critical season, as respects the water relation, is three times as long at 3,000 feet as at 8,000, making the desert conditions actually twenty-seven times as severe as those of the forested summits. The factors of soil moisture supply and atmospheric aridity, modified by slope-exposure, determine the lower limits of forest and the trees of the chaparral zone. The factors of winter cold, modified by topography through the operation of cold-air drainage, determine the upper limits of the characteristic desert species.

A Possible Mutant of the Sugar Maple: A. F. BLAKESLEE, Connecticut Agricultural College.

A single tree discovered in a roadside row of sugar maples is distinguished from the normal type by its peculiar habit of growth. The limbs are slender and branch profusely to form a close thicket of slender branchlets which end at a uniform distance from the trunk and produce an appearance similar to that of a symmetrical arbor vitæ.

A Balancing Method for Differentiating between Absorption and Transpiration: LYMAN J. BRIGGS and H. L. SHANTZ, U. S. Department of Agriculture.

In this method the potted plant is suspended upon knife-edges in a horizontal position, so that the soil part of the system is on one side of the knife-edge and the plant on the other. The system is balanced by counter-weights, and a center of gravity so adjusted as to secure the required sensibility. As water is lost through transpiration, the soil end of the system becomes lighter and rises in consequence. If the moisture content of the plant has not changed during this process, the system will be restored to its zero position by the addition to the soil centroid of a weight equal to the total loss of water from the plant during the observation period. If the weight which must

be added to the soil centroid to balance the system is less than the total loss of weight during the period, then the amount absorbed by the plant has been less than the amount transpired. If the weight required to restore the balance is greater than the loss in weight of the system, then the absorption during the period has exceeded the transpiration.

If the distances of the soil and plant centroids from the axis are known, the difference between transpiration and absorption during any period can be quantitatively determined. The location of the soil centroid can be found by observing the loss of weight, after the plant has been kept for a time under uniform conditions, so that the transpiration is equal to the absorption for the observed period. The plant centroid is determined from measurements of the area and the distance of the leaves from the axis.

This method is also adapted to the determination of the wilting coefficient for plants, which, owing to structural peculiarities, do not wilt when the moisture content of the leaves is reduced.

The Application of Wilting Coefficient Determinations to Field Work in Ecology and Phytogeography: LYMAN J. BRIGGS and H. L. SHANTZ, U. S. Department of Agriculture.

The wilting coefficient is defined as the moisture content of the soil (expressed as a percentage of the dry weight) at the time when the leaves of the plant growing in that soil first undergo a permanent reduction in the moisture content as the result of a deficiency in the soil moisture supply.

The results of 1,300 determinations have shown that species differ only slightly in their wilting coefficients when grown in the same soil. The type of soil has a great influence upon the wilting coefficient, which ranges from less than 1 per cent. in sand to over 30 per cent. in the heaviest type of clay. It is therefore evident that soil moisture determinations for the purpose of establishing available moisture in the soil are valueless unless the wilting coefficient of the same sample used in the moisture determination is also known.

The desirability of a rapid determination of the wilting coefficient of samples taken in connection with field work led to an investigation to determine whether it could be computed from physical measurements of the moisture retentivity of the soil. Several methods have been developed, the relationships established being expressed in the following equations:

$$\begin{aligned}\text{Wilting coefficient} &= \frac{\text{Moisture equivalent}}{1.84 (1 \pm 0.007)} \\ \text{Wilting coefficient} &= \frac{\text{Hygroscopic coefficient}}{0.68 (1 \pm 0.018)} \\ \text{Wilting coefficient} &= \frac{\text{Moisture-holding capacity} - 21}{2.90 (1 \pm 0.021)} \\ \text{Wilting coefficient} &= \frac{0.01 \text{ sand} + 0.12 \text{ silt} + 0.57 \text{ clay}}{(1 \pm 0.025)}\end{aligned}$$

Inhibiting Factors in Lychnis and Papaver:

GEORGE HARRISON SHULL, Carnegie Institution.

A cross between white-flowered and purple-flowered forms of *Lychnis dioica* L. (*Melandrium album* and *M. rubrum*), both from Germany, have given an F_1 predominantly white-flowered, though numerous previous crosses between other white-flowered and purple-flowered strains of this species have invariably produced only purple-flowered offspring in the F_1 . The white-flowered form from Germany, in crosses with a "recessive white" American strain, produced in one case a white-flowered F_1 , in another case a purple-flowered F_1 . In *Papaver Rhæas* white has usually proved to be recessive to colors, but in one instance a cross between deep red and white produced a completely whitish progeny in the F_1 , and the same result was also attained in a cross between two deep red parents. The latter experience suggests the existence of two complementary inhibiting factors, *A* and *B*, which have no effect except when co-existing in the same plant.

Inheritance in Capsella: H. HUS, University of Michigan.

Seedlings from a single plant of *Capsella Bursa-pastoris* can be classed in three groups: broad-leaved, narrow-leaved and linear-leaved. These forms occur approximately in the proportion 2:2:1. This proportion, which has been maintained for three generations, may perhaps be looked upon as a simple Mendelian splitting in the F_2 generation, of the *Zea* type, complicated by a defective inheritance ratio. This contention meets with the objection that the linear-leaved form represents a type thus far unreported.

The Origin of the Erect Cells in the Phloem of Abietinæ: M. A. CHRYSLER, University of Maine.

If a medullary ray in such a genus as *Pinus* is traced outward from xylem to phloem, it is well known that the marginal tracheids of the woody part of the ray may be seen to be replaced in the

phloem by nucleated cells which are somewhat elongated in the longitudinal direction, the so-called "erect cells" of the ray. From a study of the roots of seedlings it is found that various transitions between these erect cells and sieve-tubes occur. Groups of elongated cells provided with nuclei and sieve-plates are a common feature of the phloem of these young roots, and where such a group meets a medullary ray certain of the elongated cells become applied to the ray and become progressively shorter, forming the erect marginal cells, while the rest of the elongated cells give place to ordinary sieve-tubes. Thus from what may be called *primitive sieve-cells* the sieve-tubes are derived by elongation, and the erect cells of the ray by shortening.

Do the Abietinæ extend to the Carboniferous?

R. B. THOMSON and A. E. ALLIN, Toronto University.

The claims for the great geological age of the Abietinæ (see Jeffrey and Chrysler, *Bot. Gaz.*, p. 13, 1906) are based on the occurrence of *Pityoxylon chasense* in the Permian and on the supposed occurrence of *P. Conwentzianum* in the Carboniferous.

P. chasense was described by Penhallow in 1900. The pitting of the tracheids is of the Araucarian or Cordaitan type (1-3 seriate, alternate and hexagonal) and bears not the slightest resemblance to that of *Pityoxylon* as defined by Kraus (one-seriate, or opposite when two-seriate), or to that of an Abietinean form. Penhallow, however, placed this form in the genus *Pityoxylon* because of the occurrence of what he supposed were horizontal resin canals. A careful study of the type material has revealed that they are not resin canals but leaf traces quite comparable to those in certain Cordaitæ and Araucarinæ. This Permian *Pityoxylon* is, therefore, a true Cordaitan or Araucarian.

Gothan has recently shown that *P. Conwentzianum*, which is commonly attributed to the Carboniferous but whose horizon was never determined, can not be an authentic Carboniferous form.

The geological claim for the great antiquity of the Abietinæ thus fails on critical study of the two forms upon which it is based.

Ingrowing Sprouts of Solanum tuberosum: C.

STUART GAGER, Brooklyn Botanic Garden.

The paper described a case in which the sprouts of a large number of potatoes grew into and through the tubers that bore them, ramifying

freely and producing roots and small tubers within the large seed tuber. The potatoes were stored in a dry room lighted with diffuse daylight. Sprouts of one tuber never penetrated an adjacent one. Investigation failed to show the presence of any enzymes by the action of which the channels of the ingrowing sprouts could have been digested, though the epidermis of the sprouts was modified so as to resemble typical glandular epithelium, thus suggesting secretion. There was positive evidence that the sprouts made their way through the tissue by mechanical pressure. Attempts experimentally to produce penetration of tubers by potato sprouts met with success, except that the sprouts were unable to penetrate through the epidermis from the outside. These experiments, in connection with the behavior of the original abnormality, led to the high probability of a reversal of polarity in the shoots. The cause of tuber-formation in general was briefly discussed, as was also the bearing of the ingrowing sprouts on the question of the mode of emergence of lateral roots.

The Gametophytes of the Kauri: ARTHUR J. EAMES, Harvard University.

The microspore contains many supernumerary prothallial nuclei. Its branching tubes penetrate the scale-base and the axis, thence crossing the space to the nucellus which is largely eroded, with portions of the endosperm. The megaspore, developing at first within "spongy-tissue," forms a club-shaped embryo-sac, bearing 6-20 archegonia. A small ephemeral ventral canal nucleus is cut off. Fertilization occurs usually in lower archegonia, the two large male nuclei being shunted from the upper egg-cells by a cap of the megaspore membrane which is thickened rather than thin as in most conifers. The pro-embryo maintains a central position in the archegonium in contrast to the condition in other groups until at least 32 nuclei are formed. Then nuclear enlargement and wall-formation ensue, filling the archegonium. The upper 20 or more cells become suspensors, the central group, consisting of a few cells, the embryo proper, and the basal tier a marked protective cap. The large core of suspensors thrust down the two lower tiers deep into the endosperm, where in further development the cap is pushed aside and degenerates.

The Gametophytes of Australasian Podocarps: EDMUND W. SINNOTT, Harvard University.

The gametophytes and embryo of *Podocarpus Totara*, *Hallii*, *nivalis*, *dacrydioides*, *spicatus* and *ferrugineus* have been investigated. Observations

on the male gametophyte add to previous accounts, but agree in general with them. In the first four species (*Podocarpus* proper) three or four months elapse between the appearance of the megasporangium and the ripening of the fruit, and the development of the endosperm, archegonia, and embryo is much as in the Abietinæ. In all species, even a ventral-canal nucleus is uncommon. There are from eight to sixteen suspensors. The last two species (subgenus *Prumnopitys*) are very distinct. The reproductive process extends over sixteen months. The two very large archegonia are narrowed at the base. The fusion nucleus divides into four as it drops and the eight subsequent basal nuclei are irregularly arranged, as are the sixteen cells which follow them. The young embryo has a "penetrating cap." Both species of the subgenus *Prumnopitys* show a marked resemblance to *Cephalotaxus*, and further investigation promises interesting results as to the relationship of the two genera.

The following list of papers, from members of the society, or members of Section G, to be introduced by members of the Botanical Society of America, were received too late to be included in the printed program and were read by title:

Acidity as a Factor in Plant Ecology: F. V. COVILLE, U. S. Department of Agriculture.

The Cultivation of Trailing Arbutus: F. V. COVILLE, U. S. Department of Agriculture.

Ecology as Applied to the Revegetation of Overgrazed Range Lands: A. W. SAMPSON, U. S. Department of Agriculture.

The Relation of Soil Acidity to Plant Societies: A. W. SAMPSON, U. S. Department of Agriculture.

The Effect of a 2 per cent. Aqueous Solution of Antipyrin on the Cells of the Root-tip of Vicia faba: C. F. HOTTES, University of Illinois.

On the Acidity of Certain Cacti: H. M. RICHARDS, Columbia University.

Conditions Affecting the Production of Lycopin in the Tomato: B. M. DUGGAR, Cornell University.

Sensitivity in Meristematic Tissue: H. M. BENEDIOT, University of Cincinnati.

A Botanical Survey of Hartsville, S. C.: W. C. COKER, University of North Carolina.

The Biology of the Lakes of Glacier: M. J. ELROD, University of Montana.

The Cytology of Laboulbenia chartophora: J. H. FAULL, University of Toronto.

ON SOME RESEMBLANCES OF CROWN-GALL TO HUMAN CANCER¹

THE disease on which I shall speak to-day is known in this country as crown-gall, because it has been observed most frequently on the crowns of trees and shrubs, but it is not peculiar to this situation. It occurs also on roots and shoots. This disease has been known to cultivators and to plant pathologists for many years and has caused more or less injury to a variety of plants both in this country and in Europe. Of plants subject to serious injury may be mentioned: Roses, almonds, peaches, raspberries, grapes. Sometimes the plants are only dwarfed or crippled, at other times killed. Recovery, especially in certain species, is frequent. In Italy the attacked grape vines are said to live about four years.

It has been ascribed to a variety of causes, *e. g.*, frosts, wounds made in cultivating, insect injuries, fungous injuries, physiological disturbances, etc. The actual cause was not known until discovered by the writer and his associates. Team work on this disease has been carried on in the U. S. Department of Agriculture for the last eight years, *i. e.*, since February, 1904. The first successful pure culture inoculations were obtained in 1906. The organism was described and named by us in 1907.²

¹Address as retiring president of the Botanical Society of America, Washington, D. C., December 28, 1911. By invitation members of the following organizations were also present: Section G, of the American Association for the Advancement of Science; Society of American Bacteriologists, and the American Phytopathological Society.

²SCIENCE, N. S., Vol. XXV., No. 643, pp. 671-673, 1907; see also *Centralb. f. Bakt.*, 2 Abt., XX. Bd.

Addresses setting forth the parasitic nature of the organism have been given before this Society by Dr. Townsend, and before the Society of American Bacteriologists and the American Phytopathological Society by myself.³ I have also twice in public addresses before the American Association for Cancer Research called attention to certain general resemblances of this disease to malignant human tumors, namely, at the Boston meeting in December, 1909 (lantern-slide address), and again in the spring of 1910 at the Washington meeting of the Association, where I showed specimens of the disease. The whole subject so far as regards the etiology of the disease was also summed up in a big bulletin published by the Bureau of Plant Industry, U. S. Department of Agriculture, early in 1911.⁴ I may assume, therefore, that this audience is fairly well acquainted with the evidence adduced by us to prove the pathogenic nature of the organism we have called *Bacterium tumefaciens*, and therefore I shall not spend any time on this phase of the subject. Those who are not familiar with the evidence can easily obtain the necessary publications and if these are not convincing they may repeat the experiments.

In a brief way I have also published on the newer discoveries upon which I am to speak to-day, *i. e.*, in a third address before the American Association for Cancer Research,⁵ an abstract of which was published by the Department of Agriculture as Circular No. 85, Bureau of Plant Industry, and in *Zeitschrift f. Krebsforschung*,

11 Bd., 1 Heft. Since that date the subject has been studied continuously. Numerous sections have been prepared, and I will show you lantern slides of photomicrographs made from some of these sections, so that you will be able to judge for yourselves as to the bearing of the evidence.

It is hardly possible to say who first noted the superficial resemblance of overgrowths on plants to animal tumors. It probably goes far back of published records, since we have in English the word "canker" applied to certain of these overgrowths, which word is only another form of the word cancer. Also in German, the word "Krebs" is applied indifferently to these overgrowths and to malignant human tumors. It is one thing, however, to find a superficial resemblance of plant diseases to animal diseases, and quite another to establish any strict analogy. In fact, as histological studies on cancer have multiplied animal pathologists have been more and more convinced that there is no real likeness between the plant overgrowths and malignant animal tumors, and this is true enough, I believe, for club-root of cabbage, the plant disease most studied in this connection. A comparatively recent statement by Alfred Fischer that the only thing they have in common is the name (Krebs) may be taken as fairly representing the current view.⁶ I shall hope, however, to show you before I am through that they have a good deal in common, so much, in fact, that I believe we have in these particular plant overgrowths a key to unlock the whole cancer situation. In consideration of these discoveries many closed doors in cancer research must now be opened and studies on the etiology of the disease must be done over with a view to finding a parasite within the cancer cell, and separating

⁴ No. 213, "Crown-Gall of Plants: Its Cause and Remedy." To be had from the Superintendent of Documents, Government Printing Office, Washington, D. C. Price 40 cents.

⁵ Buffalo, April 13, 1911.

⁶ *Vorlesungen ueber Bacterien*, 2te Auflage, 1903, p. 277.

it therefrom by an improved technic of isolation. Before I show you any slides or describe further the discoveries made it will be necessary for me to refer briefly to the nature of cancer and certain other malignant animal diseases.

When I first called attention of members of the American Association for Cancer Research to crown-gall in 1909, the reply of some of the members was that while I had demonstrated crown-gall to be a very interesting disease it was evidently a granuloma, and not a true tumor. With this conclusion I can not agree. That you may understand why crown-galls are not granulomata I wish briefly to call your attention to the phenomena occurring in such diseases. As example of a granuloma, we may take tuberculosis. We have in this disease a focus of infection and source of irritation in the presence of a microorganism. Against this organism the body reacts with the formation in the immediately surrounding tissues of cell growths not unlike those which occur in the bottom and sides of wounds, namely, granulation tissue, hence the name granuloma. In this manner nodular growths arise, but these nodular growths are limited in extent of tissue involved, are produced from the tissues immediately surrounding the bacterial nest, are not vascularized, and soon become disorganized in their interior. In tuberculosis the blood vessels occurring naturally within the attacked area are obliterated and excluded from the tubercle; in certain other granulomata, *e. g.*, syphilitic gummata, the vessels are not obliterated, but they are distinct in other ways, *e. g.*, enclosed in a fibrous capsule. The disease is carried from place to place within the body by the migration of the microorganisms, either in the blood stream or the lymphatics or in some other way, *e. g.*, through the digestive tract. Wherever

these migratory organisms lodge they set up or may set up similar irritations with the production of similar nodules of granular tissue, the same being an effort on the part of the infected animal to overcome the disease. The point which I wish specially to emphasize is the fact that in these secondary infections the granular tissue which develops is formed out of the particular organ in which the parasites happen to lodge, and does not consist of cells brought to it from a distance.

In this respect cancers are quite different. Parenthetically I might stop here long enough to say that I shall for the purposes of this address use the term cancer in a loose, general sense for all malignant human tumors. First, because the crown-gall which I have studied seems to partake of the nature of different types of malignant animal tumors, and because I believe that when the cause of malignant animal tumors is discovered we shall find that many of the hard and fast lines of separation which the animal histologists have erected between sarcoma, carcinoma, etc., will be found untenable.

In cancer we have an enormous multiplication of certain tissues of the animal (epithelial, connective, etc.) which by continued growth crush and disorganize the surrounding tissues. These growths are more or less highly vascularized, and new vessels are formed as the tumor develops, but not to an extent sufficient to carry on the growth beyond a certain point. Usually there is a great excess of parenchyma cells in such a tumor and the blood vessels are not sufficiently numerous to nourish it properly, so that after a longer or shorter period (months or years) portions of it disorganize often into open wounds which are then readily infected by all sorts of secondary organisms with all the well-known disastrous results. This then is one striking

ing difference between granulomata and cancers, but the true nature of the cancerous development becomes more evident in the secondary tumors. The mere fact that a primary cancer has developed on some part of the body does not constitute the chief danger, since one might have such a tumor for a long time without death supervening, unless the primary growth happened to be situated in or near a vital organ. What constitutes the peculiar malignancy of cancer is the tendency to form secondary growths in various parts of the body, including the vital organs, and it is this clearly recognized danger which in modern times has led to the universal recommendation on the part of competent physicians and surgeons of the early extirpation of suspicious growths, the hope being that the surgeon may be able to dissect out all the infected tissues and thus free the patient from the disease. This is the reason why, for instance, in cancer of the breast the surgeon so carefully removes not only the infected breast, but the lymphatics for long distances away, that he may, if possible, reach beyond the unseen growing cancer strands. This also is why delayed operations for cancer are seldom successful.

In case of granulomata, as we have seen, it is the parasite which migrates. In case of cancers it is the cancer cell itself which migrates, *i. e.*, some of the body cells which under some unknown stimulation have been taken out of the physiological control of the body and have become thus, as it were, parasites on their fellow cells. There are two ways in which secondary tumors are derived from the primary tumor in cancer: (1) The primary tumor growing peripherally sends out roots or strands which bore their way through normal tissues of the body, sometimes for long distances, developing from certain

portions of these strands secondary tumors.

(2) Small groups of cancer cells are dislodged from the parent tumor and carried as floating islands in the blood stream or lymphatics to develop secondary tumors where they lodge. The first of these ways has been definitely established by observation; the second by inference, no connecting strand having been discovered. Naturally these secondary tumors, being derived from the primary tumor, tend to partake of the nature of the tissue from which the primary tumor has developed. For example, if the primary tumor be in the stomach, the secondary tumors are likely to contain glandular cells resembling those of the stomach, wherever they may be developed. This is such a striking peculiarity that it is often possible for the animal pathologist to tell from the study of his sections whether the cancer is primary or secondary, and, if secondary, in what organ the primary tumor is located. In case of tumors located in an organ containing all three of the embryonic layers or developed out of cell-rests of this nature we might have in the tumors a jumbled-up mass of all sorts of tissues—skin, bone, teeth, hair, muscle, nerve, etc. This at least is one method of explaining the embryomata.

Having found no parasite in the cancer cells, a majority of the animal pathologists have given up the idea that cancer can be of parasitic origin. For a generation the research workers fell back upon Cohnheim's hypothesis that cancers were due to the development of small fragments of tissue cut off from the parent layer during embryonal growth, to be enclosed in other tissues and lie dormant until acted on abnormally later in life by some unknown stimulus. But while studies of the animal body show that such separation of small portions of tissue from the germinal layer is not uncommon, research workers on

cancer are now generally agreed, I believe, that there are many phenomena connected with the development of cancer for which this hypothesis of Cohnheim offers a wholly inadequate explanation. Moreover, what induces these dormant cells to develop was never determined. A very favorite theory with cancer specialists has been that the cancer cell itself is the only parasite, and that no infections could be obtained on animals unless the living cancer cell were present. This hypothesis must now be abandoned owing to the discovery by Peyton Rous (1911) that sarcoma of chickens may be produced in the absence of cancer cells, *i. e.*, by cancerous fluid filtered free from all traces of living cancer cells. So far as I know he has not expressed any opinion as to the nature of the infection which has been separated from his ground chicken sarcomata by centrifuging and also by filtration through Berkefeld bougies, but in the light of the evidence we have secured from plants I believe you will agree with me that it can be nothing else than a living microorganism, minute enough to pass through the walls of the rather coarse filter.

In crown-galls I have not found the second method of formation of secondary tumors, namely, by the detachment of small fragments of the primary tumor to be carried in a stream and lodged at a distance. This method we should hardly expect to find in plants, owing to the fact that there is no rapid blood stream such as we find in animals, neither does it seem to be more than an epiphenomenon in tumor growth, the essential thing being the abnormal internal stimulus to cell division. The first method of propagation, namely, by strands, occurs, however, and parallels to my mind very strictly what occurs in malignant animal tumors, *e. g.*, in carcinoma, sarcoma, etc.

The existence of the tumor strand in crown-gall was overlooked for a long time. But last spring in making some sections of Paris daisy plants which had been inoculated with the crown-gall organism and bore both primary and secondary galls, I saw on cross-section a tumor-strand in the inner wood next to the pith between the secondary and the primary tumor and near the latter. This was about a millimeter in diameter and of a different color, *i. e.*, greenish, and easily observed by any one. Often, however, this strand is composed of a few cells only and difficult to find, even with the compound microscope. This, together with preoccupation on other phases of the research, must serve to explain why it was overlooked for so long a time. As soon as I saw this parenchyma out of place I said, "Here is a tumor strand!" and began to examine many other plants to see if it was at all constant—finding it visible to the naked eye near the primary tumor in perhaps 20 per cent. of the plants examined. The question then arose whether it was merely local, or could be traced for some distance and was of constant occurrence in the normal tissue between the primary and the secondary tumors. Since then many inoculated plants have been examined microscopically, and in all of them I have been able to find this tumor strand, although, as already stated, in many cases it is composed of a very few cells. In the Paris daisy it usually bores its way between pith and wood, or at the inner edge of the wood wedge in the protoxylem, apparently along lines of least resistance. (Lantern slides were exhibited, showing cross and longitudinal sections of such strands from the inoculated plants.)

On this strand are developed secondary tumors, apparently either where the food supply is most abundant or where the pressure of surrounding tissues is least,

yet possibly other factors are involved. Frequently the growth of the strand is rapid. In very juicy favorable material in 16 days from the date of the primary inoculation I have seen secondary tumors develop from such strands at a distance of 10 centimeters from the parent tumor. Often deep in the resistant wood the tumor strand is under great pressure. In softer parts the overlying tissues are split open, and the deep secondary tumor then comes to the surface. In the Paris daisy, when the primary tumor is on the stem, secondary tumors often develop on the leaves, and strands of tumor tissue have been traced in numerous instances all the way from the primary tumors through the stem into the leaf, and all stages of the development of the secondary tumors observed on many plants. This tumor strand boring its way through stems and leaves appears to be as much a foreign body as the roots of a mistletoe or the mycelium of a fungus. From these strands and from these secondary tumors we have isolated the same microorganism that occurs in the primary tumors and with subcultures from such bacterial colonies have reproduced the disease. The discovery of this strand affords a satisfactory explanation for the fact that the morbid growth usually returns after excision.

The second striking fact to which I wish to call your attention is that when the primary tumor occurs in the stem and the secondary tumor in the leaf the structure of the secondary tumor is not that of the leaf in which it is growing, but of the stem from which the strand was derived. If the discovery of the strand was an accident, this latter discovery was reasoned out, knowing what takes place in cancer. I said immediately, if this is a tumor-strand we ought to find a stem-structure in the leaf tumors, and the very first leaf tumors

cut showed typical examples of it. In secondary tumors occurring in the leaves as the result of stem inoculations the development of a stem consisting of a loose, rapidly growing parenchyma in the center, surrounded by wood wedges separated by medullary rays, beyond which is a cambium zone and a bark can be made out very clearly (slides exhibited). Sometimes these secondary tumors develop a very perfect stem structure; often, however, the stem is more or less imperfect with the inclusion of large parenchyma cells of the leaf, and with a great overproduction of stem parenchyma (medullary rays, etc.) as compared with the vascular portion. As this secondary tumor grows the surrounding leaf structure is destroyed, and eventually we may have a growth which bears no resemblance whatever to a leaf. Often, however, fragments of the leaf adhere to the surface of the tumor, and show an unchanged leaf structure.

These secondary leaf-tumors then, so far at least as regards the parenchymatous portion, are composed, in great part at least, of descendants of the originally infected stem-cells. The growth is an invasion of infected cells. To what extent neighboring uninfected cells are also involved is uncertain. The wood always shows hyperplasia, sometimes to a very marked degree in the vicinity of a stem tumor, and usually also in the vicinity of the tumor strand, especially if this is large. Are all of these wood cells infected? Probably not. I see no reason why we might not have changes in the plant distantly comparable to the inflammatory changes which take place in the vicinity of a malignant animal tumor, *i. e.*, an excessive multiplication of cells which while a part of the tumor are not its malignant portion. This must be left for further study.

This astonishing stem structure in leaves

is quite parallel to that which occurs in certain cancers of secondary origin where the structure of the primary tumor is outlined, albeit often only imperfectly. We might now inquire whether primary tumors produced on leaves do not have the same structure as those just described as secondary tumors. We have made needle-puncture inoculations on leaves of Paris daisy and have studied the structure of the tumors which develop and these do not have a stem structure but an irregular epithelioma-like structure derived wholly from the leaf, as may be seen from the lantern slide exhibited.

What happens finally in the case of cancer happens in crown-gall, namely, the tissues not being sufficiently vascularized, and composed of a great excess of soft and fleshy cells, are easily disorganized with the production of open wounds. In case of crown-galls on the daisy and many other fleshy plants after about two or three months large portions of the tumorous tissue decay with the formation of open wounds, subject to a variety of secondary infections.

It should be stated here, however, that in the crown-gall there are no abscess cavities such as we find often in granulomata or in such a disease as olive tuberculosis. Sometimes there is a multiplication of bacteria in the vessels in the vicinity of the needle puncture, but whether these are the crown-gall organisms or not we have not yet determined. Certain it is that when the tumor has begun to grow rapidly no bacteria or other granular matters have been found in the vessels or in the intercellular spaces. The causal bacteria occur inside the cells, which are stimulated by their presence to multiply with great rapidity and without reference to the physiological needs of the plants, *i. e.*, the plant has no direct control over the growth.

In these particulars crown-gall resembles epitheliomatous growths, while in the embryonal character of its luxuriant granulations and in its predilection for young plants and rapidly growing tissues it is more like sarcoma. The growth is a hyperplasia rather than a hypertrophy, although occasional groups of large cells occur. There can be no doubt as to the development of new vessels in the growing tumor. This is shown clearly by the anatomy of the secondary tumors. Whether the vessels are ingrowths from the surrounding tissues, or outgrowths from the tumor strand, or both, as would seem to be the case, must be left for further inquiry. The anatomy is unlike that of club-root of cabbage, where the growth consists of an enormous enlargement of a comparatively few infected cells.

I think, therefore, that we have in crown-galls a striking analogy to what occurs in malignant animal tumors, namely, to recapitulate, *the cell itself a disturbing force*, *i. e.*, an enormous multiplication of certain cells of the body without reference to physiological needs and in opposition to the best interests of the organism; a non-capsulate tumor, with absence of abscess cavities and of plainly visible parasites; peripheral growth and a well-developed stroma consisting of vessels and fibers; from this primary tumor the development of strands of tumor tissue upon which secondary tumors develop; in the secondary tumors a strong tendency to take on the structure of the organ in which the primary tumor has developed; frequent if not necessary origin of the primary tumor in bruises, wounds or irritated places; complete recovery if all the tumor tissue is extirpated, failure if it is not; in some cases spontaneous recovery. The chief difference so far made out is that in case of cancer cells we know nothing whatever as

to the cause of the abnormal growth,⁷ whereas in case of these overgrowths on plants we have definitely proved them to be due to the presence of an intracellular schizomycete which we have many times isolated and reisolated in pure culture and by means of which we can reproduce the disease at will.

The question now arises whether animal tumors might not be produced by means of the crown-gall organism. I might state here that while I believe cancer to be due to some intracellular microorganism which in its physiological peculiarities, action on the cell nucleus, etc., is like the one we have discovered, I do not maintain the overgrowths in warm-blooded animals to be due to this particular organism, for the reason that its maximum temperature for growth (daisy strain) is a little under the blood temperature of such animals. In thinking over the matter it seemed to me not unlikely, however, that with this organism I might be able to produce tumors in cold-blooded animals, and so four years ago I attempted to do it. I will show you only a slide or two made from an inoculated fish. I used for this purpose brook trout and in a very considerable portion of my inoculations I succeeded in producing ulcers in the deeper tissues where the needle entered. In this instance the needle entered the belly wall of the fish. The wound healed externally, but at the end of 21 days when the trout was dissected there was a well defined inner growth (proliferation nodule) in the connective tissue between the muscles with formation of giant cells. There were also when dissected two external sore spots,

"Some unknown force, the essential nature of which has so far completely escaped our knowledge and our comprehension, is capable of calling forth this latent power of proliferation, and the germ [cancer cell] begins to grow out of itself, like a seed that has been buried in the ground." (Dürck.)

one below the pectoral fin and the other below the anal fin, both of recent occurrence, but no throat or gill ulcers in this fish. Similar growths were obtained in the eye-socket. I showed sections cut from one of these ulcers to one of the most distinguished research workers on cancer in this country and he said "if we had this in man we should call it sarcoma." (Slides exhibited.) I propose to repeat and extend the work on trout and therefore will say but little about this phase of the investigation.

In conclusion I wish to call attention to some of the peculiarities of the microorganism (*Bacterium tumefaciens*) as determined by our cultural work. As well known to many of you, we prosecuted our studies upon the crown-gall for two years before we were able to isolate the parasitic organism. Ten years previous to this I spent six months on the subject with a similar negative result. Two obstacles of which we were unaware blocked the way. In the first place the organism in a viable form occurs in the tumor tissue of the daisy in small numbers only. If inoculations are made from crown-gall tissue, using about that amount of tissue we are accustomed to use for other bacterial plant diseases, and also for many animal diseases, the chances are that no colonies of the parasite will be obtained upon the plates. I have no doubt now that we made dozens of plates—yes, I might say dozens of separate sets of poured plate cultures, on which not a single colony of the right sort developed. It was only when we learned to inoculate our bouillons and agar plates with large quantities of the tumor material that we were able to obtain a sprinkling of colonies of the right organism. From a young, rapidly growing tumor it is always possible to obtain the organism with proper technic and sometimes in pure cultures, but

often only by using a hundred, a thousand, or a hundred thousand times too much material, if one were working with other organisms. The second obstacle is the fact that the living bacteria in the tumor tissue occur for the most part in a paralyzed condition, either as involution forms or in some other form which does not grow readily when plates are made. Cultures were made every few weeks from crown-gall tissue for two years and numerous and various bacteria were obtained on these plates, pricked off for sub-culture, studied microscopically and culturally, and inoculated into the plant with negative results, these organisms being the saprophytes which usually accompany crown-gall. The plates were usually discarded after three or four days, and so the work went on. If, however, one inoculates copiously as described, and waits a week or ten days for the paralyzed organisms to recover their vigor, he will then obtain colonies of the parasite.

Two questions arise: (1) Why does an organism which produces such striking results occur in the tissue in such small numbers? (2) What paralyzes it so that when agar plates are made from the tissues the colonies do not appear until the fourth, fifth, sixth, eighth or tenth day, and sometimes not until the twentieth day? These questions have received a good deal of thought. After a time we discovered that when the organism is grown in bouillon or other media containing sugar an acid is produced, and it then occurred to me that this acid might be the cause of the death of a large proportion of the organisms in the cells, and of the paralyzing of the remainder. Peptone water flask cultures of the organism were then grown in the presence of sugar and turned over to the chemist, who reported that the acid present was acetic acid. We found that after a time all the organisms in such cultures

were dead, and a microscopic examination showed that a large proportion of them occurred in the form of irregular club-shaped or Y-shaped bodies, *i. e.*, they had passed over into involution forms preceding their death. Subsequently we found that on adding dilute acetic acid to fresh cultures of the organism either on agar or in bouillon we could at will produce these involution forms. Ordinarily it was found on making poured plates from such cultures that all the organisms were dead, but by further experimenting we learned that if we added just the right quantity of acid, involution forms were produced and a portion of the bacteria killed, but that some remained alive and those which remained alive were paralyzed, coming up on the agar plates in the same slow manner as those from the interior of the tumors. I should have stated that although the organism comes up slowly from the crown-gall on agar-poured plates, subcultures from such colonies grow as readily as from any other easily cultivable organism, *B. coli*, for example, showing clearly that the initial slow growth is not a peculiarity due to differences in culture-media or inherent in the organism, but only one due to its previous environment in the plant cell.

Do the same phenomena occur in the plant cell? Recently from crown-gall of daisy grown for the purpose, the chemist has isolated for us an acid which he says is acetic acid. We have also found in the tissues numerous bacterial Y-shaped bodies, such as occur in our flasks when acetic acid is present. I think, therefore, we may assume, tentatively, at least, that an acid in small quantities is formed also in the cells of the crown-gall as a by-product of the bacterial growth, and that after a time this acid stops the growth of the multiplying bacteria within the cells ex-

actly as it does in the flask cultures, causing them to take on involution forms and killing the majority.

There is, as I conceive, a very delicate balance between the parasitic bacterium present in the plant and the activities of the plant cells. The cells of the plant are not destroyed by it, but only stimulated into rapid and repeated division. Upon its entrance into a cell, which must usually be by wounds, in our own experiments by needle-pricks, we may conceive the micro-organisms to multiply rapidly for a short time. The acid developed by this multiplication then inhibits the further growth of the bacteria, causing the appearance of Y-shaped bodies and the death of a certain proportion of the bacteria, sometimes nearly or quite all of them. The membrane of the bacterial cells which are killed is now permeable, and the bacterial endotoxines diffuse out into the cell. The nucleus of the cell now immediately divides, under the stimulus either of the acid or of the aforesaid endotoxines, or possibly from an excess of carbon dioxide due to the bacterial growth. There can be no doubt, I think, that carbon dioxide exists in excess in these cells, because the crown-gall tissues contain an excess of chloroplasts in the absence of any other visible means of obtaining this necessary food. These chlorophyll bodies are so abundant as often to give a distinct green color to deep tissues wherein we would ordinarily expect to find but few chloroplasts.

The next difficulty is to explain why the paralyzed bacteria carried over into the daughter cells suddenly begin a new growth. This can result, I think, only from the pouring out into the cell at the time of division of a fluid which was not previously present in it, namely, the nuclear sap which must flood the cell as soon

as the nuclear membrane disappears. Whatever the explanation may be, the bacteria take on a new growth for a short time in the daughter cells with the reproduction of the already outlined phenomena. In this way occurs within a few weeks or months an enormous overgrowth of the tumor tissue with the development of strands and of secondary tumors as already described. Using rapidly growing favorable plants, it is possible by means of a few needle-pricks carrying in the parasitic organism to obtain a tumor as large as one's fist in as short a period as six weeks. Ordinarily, however, growth is slower. Dr. A. P. Matthews, to whom I am indebted for suggestions respecting the effect of the nuclear sap on animal cells, tells me he has observed in case of the entrance of sperm cells into the eggs of star fish that the sperm retained its original form until the breaking up of the nuclear wall and the diffusion of the nuclear sap into the egg cell, whereupon the sperm took on a rapid growth.

Although we are able by means of poured-plate cultures to isolate the organism in a pure state from young crown-galls and reproduce the disease at will, we can not readily demonstrate the presence of the organism in the tissues by means of the microscope. If the bacteria were as readily seen in crown-gall tissues as they are, for instance, in the tuberculosis of the olive, the cause of the disease would have been discovered long ago. The organism is not an acid-fast organism, and when it stains at all a great variety of cell inclusions also stain and some of these derived from the cell protoplasm or from special parts of the nucleus are confusing. Its staining is also complicated by the fact of its passing over so readily into involution forms which are proverbially difficult to stain. I have seen occasionally inside of

the cells of the crown-gall motile, flexuous, rod-shaped bodies which I take to be this organism, and we have occasionally stained in small numbers in the cells bodies which closely resemble rod-shaped bacteria, but ordinarily they occur in such small numbers or take stains so vaguely and imperfectly that this method of demonstration would not be convincing to an outsider. Also sometimes we find small groups of cells filled with what appear to be semi-disorganized bacteria, as if here the bacteria had gained the mastery for a short time and then degenerated. We have not in the whole eight years obtained any very satisfactory slides, although many attempts have been made, using a great variety of fixing agents and of stains. As I have stated elsewhere, if we had depended on the microscope alone we should not have been able to work out the etiology of this disease, and the plain demonstration of the parasite in the cells must await, I think, the development of some special technic of staining whereby we may be able to mordant the bacteria in such a way that they shall take one color while the contents of the host cell takes another. Even in case of the Y-shaped bodies one is seldom able to demonstrate them in the stained cells. We have obtained the best results by an indirect method, namely, by taking clean slides and burning the surface free from all possible organisms, then putting on a little distilled sterile water, and putting into this sections of young crown-galls taken from a portion of the tissue pared free from all exterior parts, allowing the contents of the cut cells to diffuse into the water for an hour, then removing the sections, drying the fluid and staining the slide. Examining such slides under the oil-immersion objective in course of a day one finds a good many such Y-shaped bodies. We have found the best method to be

the systematic search of the whole slide, passing it back and forth under the objective. Searched in this way, about one field in four yields a Y-shaped body. Bacterial rods have also been obtained from the tissues in this way.

Various researchers on cancer have mentioned finding rod-shaped and Y-shaped bodies in cancer cells. For example, Dr. Borrel, of the Pasteur Institute in Paris, and Dr. Reese, working in the cancer laboratory at Buffalo.

These plant neoplasms contain both small-celled and large-celled parenchyma and a variety of other tissues, *e. g.*, vessels and fibers. Cell division is sometimes so rapid that the cell wall can not keep pace. (Slides shown.) Frequently two and sometimes more nuclei are present in a cell. A portion at least of the cell divisions are by mitosis; but not all, it would seem. Some queer things take place in the cells. We are now studying the mechanism of cell-division in these tumors and are not ready to report.

To conclude, suppose we had in human cancer as its cause a microorganism multiplying in small numbers within the cell, having a definite action on cell nuclei, readily inhibited by its own by-products, losing virulence easily, passing quickly over into involution forms which are difficult to stain, and which are so paralyzed that only a very small portion will grow at all, except from the very youngest cells, and these only after a considerable period of time has elapsed, and further suppose that for their growth some very special technic of isolation, or some peculiar kind of culture media were necessary, then we should have precisely the same difficult conditions of isolation and determination as have confronted us in case of this similar overgrowth of plants, and ample explanation of why expert animal pathologists have been unable to see the parasite

in their sections, and unable to cultivate it on their culture media, and consequently, have very generally reached the conclusion that it does not exist. Granted the existence of such an organism, and we have a ready explanation for the growth of the cancer cell in defiance of the physiological needs of the organism. The hitherto inexplicable occasional change in the nature of the cell-growth of tumors, *e. g.*, from epithelial to carcinomatous and from carcinomatous to sarcomatous also finds its explanation in the presence of a sensitive microorganism growing usually in the kind of cell originally infected but capable under certain circumstances of invading other types of cells.

ERWIN F. SMITH

U. S. DEPARTMENT OF AGRICULTURE

[The illustrations accompanying this address will be reproduced at an early date in a bulletin to be published by the U. S. Department of Agriculture.]

THE ROYAL ENGINEERING COLLEGE AT CHARLOTTENBURG-BERLIN

DIE Königlische technische Hochschule zu Berlin¹ is the leading school for higher learning in technical subjects in the German Empire. It is not an imperial institution; but was founded and is supported by the state of Prussia. It is under the immediate control of the Prussian University of Public Instruction.

This school covers, in general, the same ground as the Massachusetts Institute of Technology, the Troy Polytechnic, the Stevens Institute and the schools or colleges of engineering in our own state universities, including, like that of Illinois,

¹ This term has been translated into English in many different ways: the Royal Technical College; the Technical University; etc. I prefer the one I have placed at the head of this article.

for instance, a department of architecture.²

The constitutional statute as revised in 1882 declares it to be "the purpose of the Technische Hochschule to furnish a suitable higher training for technical careers in the public service of the state and the municipalities as well as for private practise in the industrial life of the nation; and further (and this is very important) to cultivate the sciences and the arts which underlie the field of technical instruction."³

The school is divided into six departments: Architecture; Civil Engineering; Mechanical and Electrical Engineering; Marine Engineering and Construction; Chemistry and Metallurgy; and General Science, including Mathematics and the Natural Sciences.

The requirements for admission have in common for all departments the certificate of graduation from a gymnasium, real-gymnasium, or higher realschule; *i. e.*, the ordinary preparatory classical or scientific college of the German empire.⁴

A year's practical work in a shop or factory is furthermore required of those who wish to take the technical degree in mechanical or electrical engineering and in a ship yard for those who wish to take marine engineering. A shorter time of practical work suffices for the candidates

² The engineering school at the University of Illinois was organized along similar lines to those of the school at Charlottenburg. Its first dean was Dr. Nathan C. Ricker, who was a student in Germany in his early years.

³ The German never loses sight of the fact that the promotion of our scientific knowledge by original investigation and research is fundamental to all successful organization of higher education.

⁴ The normal age for completing this preparatory course is 18 years. The average age, however, and the age of the majority of the graduates is nearer 19; although many finish the course at 17 and a few at 16.

in chemistry and metallurgy. This practical experience takes the place of the school shop work in our American institutions. Half of this work may be made up in vacations during the course so that the whole period of study after the preparatory school is finished is lengthened only six months by this provision.

The course of the engineering school is four years in length and leads up to a final examination, the successful completion of which entitles one to the degree of Certificated Engineer (*Diplom-Ingenieur*).

The degree of Doctor of Engineering (*Doktor-Ingenieur*) may be obtained without further attendance on systematic courses of instruction upon the presentation of a satisfactory scientific thesis "which demonstrates the capacity of the candidate for independent scientific work in the technical field," and the passing of an oral examination.

As it ordinarily requires several months' hard work to prepare such a thesis, the candidate rarely obtains his doctor's degree within a shorter time than one year after his degree of certificated engineer is obtained; though the law does not require any specified time to elapse between the taking of the two degrees.

The thesis which is required in connection with the examination for certificated engineer will not be accepted as a doctor's thesis.

With this brief statement of fact it may be interesting to compare the course and requirements of the Royal College at Charlottenburg with our own institutions.

The normal German boy should enter the gymnasium, or *realschule*, at nine years of age and complete the course by the time he is eighteen. If he then puts in a full year in a shop he will be nineteen when he enters the Engineering College with his shop work completed. By the time he has com-

pleted his four-year engineering course and obtained the degree of certificated engineer he will be twenty-three. By spending one year more he can take his doctor's degree at twenty-four.

As seen from the above account, he can shorten this time materially. First, by completing his preparatory course at 17 instead of 18, which is easy for the capable and industrious boy; second, by putting half of his practical year into the long vacations, thus saving six months; and, third, by completing his thesis for the doctor's degree in six months which is also thoroughly feasible. A student who pursues this course could obtain his doctor's degree at twenty-two instead of twenty-four.

On the other hand, the average boy takes until he is nineteen to complete his preparatory course; wastes six months, and often a year, in "enjoying his academic freedom" and takes more than the schedule time for the doctor's degree, arriving at that point in his twenty-fifth or twenty-sixth year.

Now, take the American boy who is looking forward to the doctor's degree in engineering at, say the University of Illinois. Suppose he graduates at a good Chicago high school. He will be eighteen years old if he has pursued the normal course, *i. e.*, enters the primary school at six years of age; completes the eight grades and enters the high school at fourteen, taking the regular time of four years for the full course for graduation.

He must now take four years for the ordinary course, leading to the bachelor's degree in engineering. By this time he is twenty-two. He must then take three years' graduate work for the degree of doctor in engineering, making him twenty-five years of age—*i. e.*, one year older than the German who takes the normal time.

The American boy can abridge his course one full year by completing his preparatory course at seventeen, as he can easily do if he has brains and industry. He may cut the college course by another six months if he is specially well prepared, able and industrious and may thus take his doctor's degree at twenty-three and one half.

On the other hand, the average boy slips a cog somewhere like his German brother and loses time along the way. Our statistics show that the average age of the freshman entering the University of Illinois is a little over nineteen instead of eighteen as it should be; or seventeen as it might well be; or even sixteen, as it sometimes is. Many students lose again in college and must return for a part or the whole of a fifth year before getting their first degree. Such students, however, would rarely be considered as candidates for the doctor's degree, nor would they care themselves to attempt it.

It will thus be seen that the courses in the two countries run along somewhat parallel lines so far as the formal requirements are concerned.

The German *realschule*, or *gymnasium*, is, on the whole, a more thorough and effective center of training than the American high school. The teachers are better educated and the discipline is more severe. The German boy *must work* or he is thrown out of the school. The American boy is permitted to dawdle along and fool away a good portion of his time without running any serious risk of dismissal or even of being required to take the year's work over again.

In the best American high schools with properly educated teachers the American boy has a *chance* of acquiring as good a training as his German brother, or would have such a chance, if the lazy idlers in his

class could be put in a division by themselves. Under the actual circumstances, he must use one year in college, and some high authorities would say two years, in order to get as far along in real mental training and effective knowledge as the German boy when he leaves the preparatory school.

The German engineering school gives little attention to the so-called general subjects in its curriculum. These are taken care of in the preparatory school. No languages or history appear, among the required or elective subjects. Certain general subjects which have a practical value for the engineer, like commercial law, patent law, finance, political economy, etc., are listed among the possible courses to be chosen, while opportunity is also offered for courses in foreign languages—French, Russian, English, etc.

To put our American engineering schools on a par with the German as educational institutions, we must first of all improve the quality of our preparatory instruction. This will be done, not by lengthening the college course, or by merely requiring a bachelor's degree for admission; but by insisting that the student who wishes to take up engineering studies should have a thorough grounding in the elements of a liberal education, including the mother tongue, foreign languages, mathematics, history and the natural sciences. This can all be acquired by the time the student is eighteen or nineteen years of age without spending three or four years in college after leaving the high school. Perhaps a good compromise might be effected for a time by requiring one or two years of general study in an arts course as a preliminary requirement for admission to the technical courses. If mathematics and physics, chemistry and drawing, were prescribed for this college

period it might fairly enough be fixed at two years. In this way, a five years' course, after leaving the high school, could be worked out leading to a technical degree, which might then in one more year lead to a doctor's degree. The present situation is one of unstable equilibrium. Our ultimate hope lies in the development of the public high school into an effective tory instruction.

It is interesting to note how many men come up at Charlottenburg for their final examinations and the diploma and for the doctor's degree during the year. The attendance of matriculated, *i. e.*, regular students at the Hochschule during the year ending June 30, 1911, was 2,060 (average for the two semesters). Of these, 336 passed successfully the examinations for the degree of Certificated Engineer—roughly one in six of the total number. Forty-two took the doctor's degree in engineering, *i. e.*, one in fifty.

During the week I spent in a careful study of the Hochschule and its workings I was greatly impressed by the emphasis laid on training the men to independent methods of work, and by the manifest desire to turn out, not highly trained artisans or mechanics, but independent thinkers within the field of technical pursuits—men who because of their mental development will be able to lead in whatever field they may enter. EDMUND J. JAMES

CHARLOTTENBURG-BERLIN, GERMANY,
January 1, 1912

WILLIAM EMERSON DAMON

THE death of William Emerson Damon on December 1, in Windsor, Vermont, at the age of seventy-three, recalls to his friends memories of his early days, when his enthusiastic devotion to natural history studies in general, and more especially to ichthyology and pisciculture, caused him to become the leading spirit in the establishment of New

York's first aquarium. This first venture was a department of Barnum's old Ann Street museum. It was due to Mr. Damon's persuasion that the irrepressible showman was induced to undertake this enterprise; however, unexpected difficulties were encountered in securing specimens from the South Atlantic, but few of the fish being alive when they reached New York. Finally a special craft was chartered and placed under Mr. Damon's immediate control.

This was in 1863, during our Civil War, and some very interesting details regarding this expedition have been furnished by Professor Albert S. Bickmore. Barnum, who had just acquired the "Aquarial Gardens" in Boston, wrote to Professor Agassiz, of Harvard, that if the latter had an assistant whom he would like to send along to collect specimens for the Museum of Comparative Zoology in Cambridge, all facilities would be accorded to him. This offer was accepted by Agassiz, who selected Professor Bickmore as his representative. The little fishing-smack chartered for the trip was given the high-sounding name *Pacific*. Its equipment, however, was of the simplest, not even a chronometer being on board, so that when, after coasting along until Cape Hatteras was reached, the course was laid due east, and the ship passed out of sight of land, there was no means of determining its exact position. Fortunately, half-way toward Bermuda, an East-Indiaman was met, and the adventurous seamen were able to learn their precise latitude and longitude.

On the arrival of the little craft in Bermuda, Professor Bickmore writes:

As we came near Port Hamilton, the principal harbor, a number of native boats put off to board us, for what purpose we were at a loss to imagine, until one more skilfully managed than the others came alongside, and its black crew offered to aid us as agents. "What for?" we asked; to which came the rejoinder: "Why, when we saw how you could sail in a strong breeze, we felt sure you were a 'blockade-runner' loaded with tobacco."

When the entirely peaceful intentions of the newcomers were made plain, the authorities facilitated their operations and some 600

fine specimens were secured, and safely brought to New York. The beautiful Bermuda Islands were then but little known to New-Yorkers and the enthusiastic account of their charms given by both Mr. Damon and Professor Bickmore undoubtedly helped much to make that region popular with New-Yorkers and Bostonians.

To this first aquarium venture succeeded another, which was housed for some years in a building on the site now occupied by the Herald Square Theatre. A most appropriate banquet celebrated the opening of this aquarium, the menu of fifty-three courses consisting exclusively of fish. With this foundation Mr. Damon was largely interested and when, finally, the present well-equipped aquarium in Battery Park was established his advice and council were eagerly sought and he was given a deciding voice in the choice of the director.

There can be no doubt that if Mr. Damon could have found an opening enabling him to devote all his time and energies to natural history he would have earned a world-wide reputation in this field, but a leading jewelry house would have lacked his valuable services as part owner and credit-man, services extending for forty years. Nevertheless, his interest in these studies was always great and he found time to make many contributions to the progress of this branch of science. His book entitled "Ocean Wonders" records a number of very interesting experiences gained during his early researches. During his business career he was exceedingly fond of making pedestrian excursions in the environs of New York City, and thus acquired an exceptionally thorough knowledge of the formation of the land in this territory.

His lively interest in scientific pursuits and the recognition accorded him in the scientific world is shown by his membership in the New York Microscopical Society, the Royal Microscopical Society of London, the New York Mycological Club, the Scientific Alliance of New York, the New York Naturalists' Club and the New York Zoological Society. He

was also a member of the New England Society. He is survived by a widow.

GEORGE F. KUNZ

MEMORIAL TO MRS. ELLEN H. RICHARDS

THE third annual meeting and luncheon of the Home Economics Association of Greater New York, held on Saturday at the National Arts Club in that city, took the form of a memorial to Mrs. Ellen H. Richards, late of the Massachusetts Institute of Technology and president of the Lake Placid Conference of Home Economics and the American Home Economics Association. The literary program at the luncheon was in charge of Professor Helen Kinne, of the School of Household Arts, Teachers College, the president of the New York association. At the last annual meeting Mrs. Richards was present as the guest of honor and gave an address on the "Conservation of Human Resources." Miss Kinne in introducing one of the speakers, said that probably there was no member of the club whose life had not been touched and quickened by Mrs. Richards. For herself, she said, she had two mental pictures of Mrs. Richards, one in her laboratory at the Institute of Technology, and the other in her home with the flowers.

The first speaker was Miss Margaret Maltby, professor of physics in Barnard College. She told of her first contact with Mrs. Richards while she studied at the Institute in 1887 and of the constant thoughtfulness of the only woman teacher there for the girl students. She said:

Mrs. Richards in an unusual degree combined the qualities of the prophet, the scientist and the practical optimist. She was constantly anticipating lines along which advance would be made. Her imagination was based on a solid foundation of scientific fact and her prognostications were seldom wrong. Her interests were broad and were not confined to any one science. This was shown by her study of medical books, by her use of the weather charts which came daily to her home, and by her activities in many scientific societies. With all this there was a sense of proportion, an instinct for what was feasible, a practical method of attack, a wonderful power of analysis, which was

often astonishing. She was a pioneer in scientific management in the case of the individual as well as of the institution and aimed for the maximum of efficiency for the individual and the race. Environment as expressed in food, shelter and clothing was but the means to an end, the betterment of the race.

Mrs. Mary J. Lincoln, first principal of the Boston Cooking School, told of Mrs. Richards's help in the early days of that institution (now merged with Simmons College), how she sometimes lectured at the school and more often the pupils went to her. At a later period when Mrs. Lincoln was preparing a text-book for public schools, Mrs. Richards gave advice and read proof. "Be careful, that may not be so in ten years," "Better say, 'so far as we know now,'" were some of her comments which prove how her own words were to be trusted.

Of particular interest was the announcement made by Mrs. Caroline Weeks Barrett, chairman of the Ellen H. Richards Home Economics Fund committee. This committee is soon to make definite announcement regarding the memorial to Mrs. Richards which will take the form of a fund to be administered for research and publication for advancing the interests of the home.

We could not think of putting up a dead thing as a memorial to Mrs. Richards, a bronze tablet or even a building. She was a living argument for home economics. How shall we keep her alive? We must give her earthly immortality through a living memorial, something which shall continue to do Mrs. Richards's work with Mrs. Richards's spirit. For this woman who believed in the impossible and helped it to come to pass it is not impossible for us to raise a hundred thousand dollars in dollar subscriptions from those who have felt her influence, to be invested by a board of trustees and used under their direction to establish the *Journal of Home Economics* and later for lectureships, research and publication according to the needs of the time. The collection of funds by personal canvass is soon to be initiated in a country-wide campaign which will enlist committees numbering over a thousand persons who will seek this uniform democratic contribution from men and women interested in advancing the welfare of the home through a memorial to this

woman who as scientist and social engineer did so much for the home.

SCIENTIFIC NOTES AND NEWS

AMONG the British New Year's honors are knighthoods conferred on Professor W. F. Barrett, F.R.S., formerly professor of physics in the Royal College of Science, Dublin, and Professor E. B. Tylor, F.R.S., emeritus professor of anthropology in the University of Oxford.

M. LIPPMAN has been elected president, and Professor Guyon vice-president, of the Paris Academy of Sciences.

THE Academy of Sciences at Bologna has awarded the Élie de Cyon prize of 3,000 lire to Professor E. A. Schäfer, of Edinburgh.

THE senate of St. Andrews University has resolved to confer honorary degrees *in absentia* upon gentlemen chosen for the degrees on the occasion of the celebration of the five hundredth anniversary of the foundation of the university in September last, but who were unable to be present. Among them is Dr. Charles D. Walcott, geologist, and secretary of the Smithsonian Institution.

COLUMBIA UNIVERSITY has designated as Jesup lecturer for 1912-13 Professor H. T. Morgan, of the department of zoology. His lectures will be delivered at the American Museum of Natural History. Professor W. P. Montague, of the department of philosophy, has been appointed to deliver the Hewitt lectures at Cooper Union in the spring of 1913.

MR. RAYMOND A. PEARSON has resigned the office of commissioner of agriculture of the state of New York.

PROFESSOR JOHN B. WATSON, of the Johns Hopkins University, has recently been granted a three years' appointment as a research associate of the Carnegie Institution of Washington, in order that he may study the migratory and other instincts of the sea-gulls of the Tortugas, Florida.

AN expedition to Montego Bay, Jamaica, is about to be undertaken by the department of marine biology of the Carnegie Institution of Washington. In addition to the director, the

investigators will consist of Professors David H. Tennent, Gilman A. Drew, Robert Tracy Jackson, H. L. Clark, H. E. Jordan, R. L. Cary and E. E. Reinke. Mr. George Gray, of Woods Hole, will accompany the expedition as collector.

PROFESSOR M. M. METCALF, head of the department of zoology of Oberlin College, has been granted leave of absence for the second semester to carry on research work in the Marine Laboratory of the University of California.

FREDERICK STARR, associate professor of anthropology at the University of Chicago, returned on January 1 from a four months' journey through Korea. Professor Starr has been made a Commander of the Order of Leopold II., by King Albert, of Belgium.

MR. WILFRED H. OSGOOD, of the Field Museum of Natural History, accompanied by Mr. Malcolm P. Anderson, sailed on January 27 from New Orleans to Colon, *en route* to the west coast of South America and the Peruvian Andes. They will spend six to nine months collecting mammals and birds and studying the general faunal conditions in that region.

PROFESSOR C. V. PIPER, of the United States Department of Agriculture, has returned to Washington after a year's absence in the orient. Six months of this time were spent in the Philippine Islands investigating the possibilities of producing hay in the Philippines for the use of army horses. The remaining time was devoted mainly to a study of the agricultural conditions in India. Professor Piper brought back with him a large lot of seeds, principally grasses and legumes, which promise to be of value in the southern states and West Indies.

THE eighth lecture of the Harvey Society series will be delivered by Professor T. W. Richards, of Harvard University, on Saturday, February 3, 1912, at 8.30 p.m., at the New York Academy of Medicine, 17 West 43d Street. The subject is: "The Relations of Modern Chemistry to Medicine."

PROFESSOR W. L. TOWER, of the University of Chicago, delivered a lecture on December

20 to the members of the Science Club of the Kansas State Agricultural College at Manhattan on "The Modification of the Germ Plasm and Inheritance."

PROFESSOR D. H. TENNENT, of Bryn Mawr College, gave an afternoon and an evening lecture at Oberlin, on January 17, upon "Variation and Heredity in Echinoderms," basing his discussion on his hybridization experiments and the cytological analysis of their results.

DR. BARTON WARREN EVERMANN, chief of the Alaska Fisheries Service, U. S. Bureau of Fisheries, lectured before the Buffalo Society of Natural Sciences on Friday evening, January 19, on "The Alaska Fur-seal and the Fur-seal Question." He strongly approved the government policy of killing the surplus 3-year-old males, after making ample reservations for breeding purposes.

PROFESSOR LAFAYETTE B. MENDEL, of Yale University, gave an illustrated lecture before the Columbia University Chapter of the Sigma Xi Society on January 18, on "Nutrition and Growth."

PROFESSOR J. MCKEEN CATTELL, of Columbia University, gave the foundation address at Indiana University on the morning of January 19. In the afternoon he spoke before the faculties on "Grades and Credits," and in the evening addressed the Society of Sigma Xi. On January 22, he gave an address before the faculties of the University of Illinois on "The Administration of a University," and in the evening discussed the question with the committee charged with framing a constitution for the university. On January 5, Professor Cattell gave an address at Lehigh University and in the evening addressed the faculties of Lehigh University and Lafayette College.

THE department of Natural History of the College of the City of New York announces the following public lectures, which will be given on Thursday afternoons at 4 o'clock:

February 8—Professor N. L. Britton, director of the New York Botanical Gardens: "Scenic and Floral Features of Cuba."

February 29—Dr. C. H. Townsend, director of

the New York Aquarium: "The Voyage of the *Albatross* to the Gulf of California."

March 7—Dr. C. William Beebe, curator of birds, New York Zoological Park: "Adventures of an Ornithologist in the Far East."

March 21—Dr. R. H. Lowie, assistant curator of anthropology, American Museum of Natural History: "An Ethnologist in the Field."

THE Naples Table Association for promoting Laboratory Research by Women calls attention to the opportunities for research in zoology, botany and physiology provided by the foundation of this table. The year of the association begins in April and all applications for the year 1912-13 should be sent to the secretary on or before March 1, 1912. A prize of \$1,000 has been offered periodically by the association for the best thesis written by a woman on a scientific subject, embodying new observations and new conclusions based on an independent laboratory research in biological (including psychological), chemical or physical science. In April, 1911, the prize was named the Ellen Richards Research Prize. The sixth prize will be awarded in April, 1913. Application blanks, information in regard to the advantages at Naples for research and collection of material, and circulars giving the conditions of the award of the prize will be furnished by the secretary, Mrs. A. D. Mead, 283 Wayland Ave., Providence, R. I.

The chairman of the finance committee of the New York Academy of Medicine, in sending out to members the treasurer's report, states that \$110,000 has been raised by subscription from about one fourth of the members, and that it is expected to collect about double that sum within the academy in order to pay for the real estate purchased as a site for the proposed enlarged building, before appealing to the general public for funds.

THE extension of the Horniman Museum, Forest Hill, consisting of a lecture hall and a new library, the gift of Mr. E. J. Horniman, son of the donor of the museum, was opened on January 27, by Sir Archibald Geikie, K.C.B., president of the Royal Society.

MR. ROBERT WILCOX SAYLES, in charge of the geological section of the Harvard University

Museum, has given the sum of \$5,000 to the Seismological Society of America, to aid in the publication of the Society's *Bulletin*.

THE Field Museum of Natural History, Chicago, has acquired recently, through purchase, the herbarium and botanical library of the late J. H. Schuette, of Green Bay, Wisconsin. The collection comprises 15,000 to 20,000 carefully prepared and fully labelled herbarium specimens, principally from Wisconsin, well representing the flora of the state. In addition to the general collection there is a valuable series of native American roses, the particular group of plants in which Mr. Schuette was for many years deeply interested and to which he gave critical study.

AMONG the dispositions of the will of Dr. O. M. Lannelongue, professor of surgery at the University of Paris, are the following: An annual sum of \$100 is left to the University of Paris, the same sum to the Faculty of Medicine for assisting necessitous students, and a sum of \$35,000 for the establishment of a museum, for which material had already been collected, in his native town, Castéra-Verduzan. Various other benefactions are conferred upon the town of Castéra-Verduzan. The residue of the property is to go towards the creation of some national or international work of a social or scientific order.

MR. CHARLES G. ABBOT, director of the Smithsonian Astrophysical Observatory, has returned to Washington from Bassour, Algeria, where he has been making astrophysical observations, in regard to the solar constant of radiation. The observing station in Bassour was established in July, 1911, when Mr. Abbot and his field assistant, Professor Frank P. Brackett, of Pomona College, arrived in Algeria, and observations were continued until the end of November. From previous work at Washington, Mount Wilson and Mount Whitney, it had been determined that the sun was probably a variable star, and that apparently its radiations frequently fluctuated from 2 to 5 per cent., during irregular periods of from five to ten days duration. Although strongly indicated by the work on Mount Wil-

son, the result was so important that it seemed necessary to test it further, by means of simultaneous independent observations held at Mount Wilson and some other high altitude station remote from there, where an equally cloudless atmosphere existed. These duplicate observations would eliminate all errors due to local atmospheric conditions. Mr. Abbot made complete determinations of the solar constant of radiation for forty-four days, in Bassour, while his assistant, Mr. L. B. Aldrich, made similar measurements at Mount Wilson, Cal. The two observing stations were separated by a distance nearly equal to that of one third the circumference of the earth. Unfortunately some cloudy weather was encountered at each of the stations, but the records of about thirty days will be available for comparison. If it seems necessary to make additional measurements it will be possible to continue the work this year, during June, July and August.

MORE than 200,000,000 barrels of oil, with a value of nearly \$128,000,000, were produced in the United States last year, according to David T. Day, of the United States Geological Survey, in an advance chapter on petroleum from "Mineral Resources of the United States" for 1910. The petroleum industry in the United States, says Dr. Day, has been characterized by a phenomenal increase each year for the last four years. Each year's gain over that of the year before has been so remarkable as to lead to the belief that the limit of production had been reached, but the increase has continued rapidly. After varying between 50,000,000 and 60,000,000 barrels annually in the decade between 1890 and 1900, the oil output was over 63,000,000 barrels in 1900 and increased to 88,000,000 barrels in 1902. In 1903 it passed the 100,000,000-barrel mark, in 1904 it was over 170,000,000 barrels, and in 1905 nearly 135,000,000 barrels. After a slight decline in 1906 the output rose again, in 1907 reaching 166,000,000 barrels. It was 178,000,000 barrels in 1908, 183,000,000 barrels in 1909, and 209,556,048 barrels in 1910, a gain of 14 per cent. over the record output of 1909. This brought

the total output since the beginning of the petroleum industry to more than two billion barrels. The United States is now by far the greatest oil-producing country; in fact, it produces more than all the rest of the world together. In 1910 the wells of this country yielded nearly 64 per cent. of the total production, Russia scoring a very poor second with about 70,000,000 barrels, or 21 per cent. The production of other countries is comparatively negligible, the third on the list, Galicia, contributing only 3.87 per cent. of the total. The excess of the petroleum production of the United States over the normal demand is shown by the fact that the 209,556,048 barrels produced in 1910 brought a smaller return—\$127,896,328—than the 183,170,874 barrels in 1909, which was valued at \$128,328,427. The even smaller output in 1908, 178,000,000 barrels, was valued at still more—\$129,079,184. As the production has increased the average price has gone down from more than \$1 a barrel in 1900 to 61 cents in 1910. These repeated great increases in oil production have been due to the successive development of four great petroleum fields farther west than the old productive centers. By 1900 the country had adapted itself to the influx of oil from western Ohio and Indiana; then came in rapid succession the development of the Gulf field in Texas and Louisiana, the Mid-Continent field in Oklahoma and Kansas, and the Illinois field. In the meantime California's production had been increasing so rapidly that it became the dominant feature of 1909 and 1910, outstripping the production of any other state and promising to retain this supremacy in the future. The trade effect of these developments was largely discounted by the small proportion of gasoline and kerosene yielded by the Gulf and California oils and it was only when the superior character of the Mid-Continent oil was recognized that the middle western contributions began to be taken seriously in the general trade. Geographic and technical factors put California petroleum at a disadvantage compared with the eastern supply,

but the great production has compelled such advances in refining methods as to make it reasonably certain that California will in the future yield good refined products, including lubricating and illuminating oils.

THE results of the latest tests on reinforced concrete, conducted in the College of Engineering of the University of Wisconsin, have just been published by the university. In this bulletin suggestions are made as to the most economical mixture of cement, sand and gravel in making the concrete. It also contains data concerning the strength of different forms of reinforced columns. The loads that may be safely used in designing reinforced concrete columns and the strength of columns resting upon small footings are also dealt with, and conclusions given as to the behavior of the latter. The work in this field has been in progress for about ten years at the University of Wisconsin and the bulletin just published supplements one published about three years ago.

UNIVERSITY AND EDUCATIONAL NEWS

THE directors of Bryn Mawr College have formally accepted the bequest of \$750,000, made by the will of Emma Carola Woerishoffer, of New York, who was killed in an automobile accident last summer. The whole sum has been constituted as a permanent endowment fund, to be named the Emma Carola Woerishoffer Endowment Fund. A scholarship has been founded at the college in memory of Miss Anna Hallowell, of Philadelphia, by her family. The interest of the \$2,500 which is given will be used as a scholarship for an undergraduate student each year.

THE sum of \$50,000 has been given to Beloit College by Mrs. Rufus H. Sage, of Chicago, and will be applied to the endowment of the chair of English literature. The total endowment of the college—in active, interest-bearing securities—is now increased to \$1,251,000, aside from the value of the buildings.

THE University of California announces the establishment by Mr. F. M. Smith, of Oakland, California, of a research fellowship for

investigation of certain problems incident to the growth of cities in the San Francisco Bay region. Attention is to be directed especially to questions relating to the development of parks, playgrounds and other community interests demanding particular consideration of space available for growth. The stipend of the fellowship is \$1,000 per annum, and an additional sum of \$500 annually is provided for expenses of the investigation.

BUILDING operations on the new auditorium of the University of Michigan, made possible by Regent Hill's bequest of \$200,000, will soon be under way. The site has been chosen with a view to commanding a convenient approach when the campus extension plans shall have been carried out. The auditorium, with its two galleries, will have a seating capacity of 5,500.

M. GEORGES LEYGUES has given 25,000 francs to the University of Paris for the new Institute of Chemistry.

THE faculty of the College of Arts and Sciences of the University of Maine has made a change in the requirements for the B.A. degree, abolishing the requirement of ten hours in the classical department. Hereafter, neither Latin nor Greek will be required for admission to the college, nor for the B.A. degree. A broad group system has been adopted within which a student, under the advice of his major instructor and with certain restrictions, may elect his own course.

THE board of trustees of the College of the City of New York has authorized the opening of the college courses to mature and properly qualified applicants who do not wish to pursue the full curriculum leading to a degree. In the department of chemistry special courses are offered in analytical, industrial, organic, physical and electrochemistry with opportunities for investigation. Full particulars may be had by addressing Professor Charles Baskerville, College of the City of New York.

ANNOUNCEMENT is made that the formal inauguration of Dr. John Grier Hibben as president of Princeton University will take place early in May. Dr. Hibben will continue to

give his course of lectures on philosophy under the auspices of the Graduate School, and it is expected that he will continue to give at least one course to the undergraduates.

DR. HENRY LOUIS SMITH, president of Davidson College, has been elected president of Washington and Lee University.

MR. H. R. FULTON, associate professor of botany in the Pennsylvania State College, has been elected to the professorship of botany and vegetable pathology in North Carolina College of Agriculture and Mechanical Arts.

BEVERLY W. KUNKLE, now instructor in the Yale Sheffield Scientific School, has been appointed to the chair of zoology at Beloit College to assume his duties in September.

IN Macdonald College, Ste. Anne de Bellevue, Quebec, the following have been appointed to fill the positions named: *Lecturer in Biology*: W. P. Fraser, M.A., Pictou, N. S. *Lecturer in Poultry and Poultry Management*: M. A. Jull, B.S.A., at present Live Stock Commissioner of the Province of British Columbia. *Assistant in Animal Husbandry*: W. J. Reid, B.S.A. *Assistant in Biology*: Peter I. Bryce.

DISCUSSION AND CORRESPONDENCE

"PHENOTYPE" AND "CLONE"

IN calling attention to the frequent misuse of the words "genotype" and "pure line," Jennings says¹ that the word "phenotype" "designates a group of organisms which in outward appearance seem to belong to one type, although in hereditary constitution they may actually differ greatly. *Genotype*, in Johannsen's usage, is not directly contrasted with phenotype," etc.

As I have also used "phenotype" with the meaning indicated by Jennings, I did not recognize the fundamental misconception involved in the quotation given above, when I wrote my note² in response to the article from which this quotation is taken. My attention has been called to this point by Dr. Johannsen, and it seems best to set the matter straight at once, in connection with the at-

tempt made by Jennings and seconded by myself, to restrict to their original meanings, the other terms introduced by Johannsen. "Phenotype" and "genotype," when both are rightly used, are *contrasted terms*, both being *abstractions* referring to the *type* to which an individual or group of individuals belongs, and *not to the group of individuals* belonging to that type. To illustrate the use of "phenotype" in its correct sense, reference may be made to the F_2 of a Mendelian hybrid. When an F_1 hybrid whose genotypic constitution may be represented by the formula, $XXAaBb$, is self-fertilized or crossed with another individual having the same formula, there will be possessed by different individuals among the offspring nine different genotypes, but only four different phenotypes. The nine genotypes may be represented by the formulae: $XXAABB$, $XXAABb$, $XXAaBB$, $XXAAbb$, $XXaaBB$, $XXAaBb$, $XXAabb$, $XXaaBb$ and $XXaabb$. The four phenotypes may in similar manner be indicated by the formulae: XAB , XAb , XaB and Xab . As the "phenotype" is the "type of the phenomenon"—the type of that which actually appears—there must always be as many distinguishable groups of individuals as there are phenotypes; hence, the readiness with which the word "phenotype" has been misinterpreted and applied to the group of apparently equal individuals instead of the constitution or assemblage of characteristics with respect to which such a group of individuals is apparently homogeneous.

There is at present no satisfactory word universally applicable to all groups of individuals possessing the same phenotype—the concept for which the word "phenotype" itself has been misused. The words "species" and "sub-species" used by taxonomists are applicable, at least in some cases, to groups of such phenotypically equal individuals, but no one would think at present of applying either of these words to all the numerous slightly differentiated groups which the geneticist is now able to distinguish and with which he is obliged to work. A short and appropriate word for all such groups of individuals,

¹ SCIENCE, December 15, 1911.

² SCIENCE, January 5, 1912.

of whatever degree of differentiation, is greatly needed.

In my discussion of "clone" as a suitable name for any group of plants or animals which has been formed from a single original individual by purely vegetative methods of reproduction, I suggested the restriction of the term to groups of genotypically identical individuals. Further consideration convinces me that this restriction is highly undesirable because it is impracticable. It would be quite impossible to know for a certainty that two twigs used as cuttings or cions from the same tree had the same genotypic constitution, and consequently there could be no security in the assumption that they were members of the same clone, if the definition given in my previous note should be maintained. I wish, therefore, to offer an amendment to that definition by striking out such restriction. The definition may then read: "Clone, a group of individuals traceable through asexual reproductions (including parthenogenesis when unaccompanied by genotypic segregation) to a single ancestral zygote, or else perpetually asexual." This definition puts the word "clone" on exactly the same footing as the expression "pure line," making it a purely genealogical term and involving no implication whatever as to the genotypic equality of the individuals included in the single clone.

GEO. H. SHULL

THE PRIBILOF FUR SEAL HERD

TO THE EDITOR OF SCIENCE: In SCIENCE of October 27, 1911, page 568, there appears an article entitled, "The Pribilof Fur Seal Herd, and the Prospects for its Increase," signed by C. H. Townsend, member of the Advisory Board of the Fur Seal Service.

Dr. Townsend in his article handles rather severely certain persons "whose opinions upon the subject are of little value." I cheerfully admit that I am one of the persons referred to, and I shall be equally frank to say that I am sorry Dr. Townsend feels the way he does, for at the bottom we both desire the same thing, namely, the rehabilitation and preservation of the fur seal herd.

A scientist who desires his opinions upon any subject to be of value must, above all, be accurate as to his facts. In his article Dr. Townsend tells us that "The hook-worm is one of the contributing causes to heavy annual losses among the young seals born on sandy areas."

In view of this statement, I would like to call Dr. Townsend's attention to the report of Walter I. Lembkey, agent in charge of the Alaskan Seal Fisheries, dated December 14, 1906 (page 274), printed as Appendix A to Hearings on House Resolutions No. 73:

Inquiries have been made recently of the Department concerning the present effect of *Uncinaria* on the seal pups, and it has been strongly intimated by certain persons that thousands of pups die annually from the ravages of this parasite, of which no report is made in the agent's report. The fact is that *Uncinaria* has not now, nor has had for several years past, any known existence on the islands. This statement is justified by actual and careful examinations during the last three years.

Also to the report of Harold Heath's "Special Investigation of the Alaska Fur Seal Rookeries, 1910" (same publication as cited above, page 1223):

In earlier times the ravages of the parasitic worm *Uncinaria* were especially noticeable on the Tolstoi sand flat and portions of Zapadni; but in recent years, due to shrinkage of the herd, these areas have been abandoned. Very few cases were noted by Dr. Chichester in 1909, and not one was detected this year. The dead pups dissected were seemingly in a perfectly normal condition, their emaciated appearance and empty alimentary canal indicating death from starvation.

On the question of the closed season Dr. Townsend is especially severe. He tells us that a cessation of slaughtering seals would be "positively dangerous," because of the rapid increase in fighting males. I once made the suggestion to him, favorably received at the time, that as the old bulls haul out on the breeding grounds some ten days in advance of the females, it would be rather a simple matter for the agent in charge and his Indians, armed with a few modern rifles, to dispose of these dangerous surplus bulls. But a far

better answer is found in the fact that years before the club and the gun were used upon the seals the herds thrived and increased, and the more powerful bulls fought their way into the breeding grounds and did their part in creating a strong and virile race that was numbered by millions instead of the few thousands that are left to-day.

The tide of life on the fur islands has reached its lowest ebb. Dr. Townsend himself says that "the stock of females has reached the lowest limit in the history of the Islands." The objectionable persons, of whom I am one, have based their beliefs and opinions not on the conflicting reports of scientists, but on the broad principle that when any species of wild life has become so depleted as to be in danger of extinction, the best remedy is to let it absolutely alone. In this connection I wish to quote President David Starr Jordan, of Stanford University, and also a member of the Advisory Board of the Fur Seal Service:

With men, as with animals, "Like the seed is the harvest." In every vicissitude of race of men or of breed of animals, it is always those who are left who determine what the future shall be.

All progress in whatever direction is conditioned on selective breeding. There is no permanent advance not dependent on advance in the type of parenthood. There is no decline except that arising from breeding from the second-best instead of the best.

The survival of the fittest in the struggle for existence is the primal moving cause of race progress and of race changes. In the red stress of human history, this natural process of selection is sometimes reversed. A reversal of selection is the beginning of degradation. It is degradation itself.

Natural conditions should be the rule, and all killing of selected males for commercial purposes should absolutely cease until the tide of increase in the fur seal herd has once more set toward the flood.

MARSHALL McLEAN,

Member of the Camp Fire Club's Committee on Game Protective Legislation

NEW YORK,
January 2, 1912

QUOTATIONS

THE PRESIDENCY OF THE UNIVERSITY OF MONTANA

For the first time the state board of education permits me, although solely through newspaper reports, to have a statement of considerations which influenced its members in voting "not to renew Dr. Duniway's contract at the close of the year, September 1, 1912."

To the extent that official propriety permits me, and without entering into controversies with my superior officers, I feel obliged to call attention to certain features of this report.

The basis for the action of the state board is said to be primarily a report of the university committee, following an investigation of university affairs made in Missoula on October 22 and 23. It should be borne in mind that this so-called investigation was made without notice to the president of the university, and at a time when he was out of the state. The summing of members of the faculty, of alumni and of students, was prearranged by the chairman of the committee. Under the circumstances there was no opportunity, and there seems to have been no expectation to extend the scope of the inquiry to make it fairly representative of the prevailing opinions and the essential facts which ought to have been considered. Any fair-minded person is entitled to draw his own conclusions concerning such a situation.

It will conduce to clearness if the report of the committee, as published, is briefly considered, point by point. Its essence is found in these statements: First: "We find there is a spirit of unrest and dissatisfaction existing between the student body and the president"; second, "There is dissatisfaction between the alumni and the president"; third, "A lack of cooperation and coordination existing between the president and a large portion of his faculty"; fourth, "We find that the president is exceedingly unpopular among the high school students of the state." A fifth point is added, said to be derived from the general discussion, "That President Duniway does not visit classrooms to ascertain at first-hand the

value of the services of any professor." Perhaps a sixth point should be enumerated to the effect that these other points "seriously retard the growth of the institution and impair the usefulness thereof."

With respect to the allegation that there is a spirit of unrest and dissatisfaction existing between the student body and the president it would be interesting to know just how many and just what students were examined upon this point. As far as such information has come to the president by indirection and rumor, it would appear that a considerable proportion of such students were those who have personal reasons for "dissatisfaction." In the course of administering a clean athletic policy and reasonable standards of scholarship, together with correct principles of conduct, the president has found it necessary to deal more or less sternly with some, at least, whose opinions seem to have impressed the committee. The process that was used to obtain student sentiment is noteworthy, chiefly because of the absence of students whose chief concern is scholarly work or scholarly distinction. To the members of the faculty it has appeared somewhat remarkable that the management of general student affairs in the university has been accompanied with so little friction and with so much genuine good will.

With regard to the second point on the alleged dissatisfaction between the alumni and the president, it is noteworthy that the "request of certain of the alumni" which is said to have produced this investigation was signed by two members of the class of 1911, the other three being undergraduates. One of these graduates had been severely disciplined for various delinquencies, both under the preceding and present administrations. How many alumni, apart from these two, testified is quite unknown to the president. A few persons seemed to be considered "the alumni." It should be added that some of the alumni, like some of the students, have been "dissatisfied" with the president's enforcement of athletic eligibility rules and his neces-

sarily vigorous efforts to prevent professionals from getting places on football teams. A very few also have been displeased because the president declined to perpetuate a so-called honor society, oathbound and secret in character, composed of three members of the faculty and a handful of third and fourth year men. Such an organization was not a healthy influence with regard either to the general student body or to the faculty, whatever may have been its ideals and hopes in its earlier history. A very few also, when they heard of discipline being applied to members of their fraternity chapters, were more or less critical. Certainly a judicious inquiry would consider questions of the animus and credibility of witnesses. Finally, it should be remarked that there has been no expression by "the alumni" of dissatisfaction with the president. On the contrary, many of them have been exceedingly helpful and most cordial in advancing the plans of the president.

With regard to the third point on lack of cooperation between the president and "a large portion of his faculty," it is difficult to see any real justification for such a statement. In an authorized interview published in the *Missoula Sentinel* on October 25 the chairman of the committee is quoted as saying that he "desires to correct the statement published by the *Sentinel* yesterday that any of the faculty had been disloyal to Dr. Duniway." The members of the faculty who were summoned before the university committee voluntarily and individually told the president that they had not been dissatisfied with the administration and that they had so testified to the committee. It would seem that the committee has construed a reasonable amount of candid difference of opinion such as right-minded members of any faculty are sure to feel into "lack of cooperation and coordination." If such a supposition does not fully explain this point is it not reasonable to think that what psychologists call "reaction to external stimuli" might have been produced in a few cases where members of the board let it be known that they were looking for criticism?

Certainly, until October last the president had felt that his relations with the faculty were unusually satisfactory, and he has had very little reason to change his opinion since that time.

The fourth point in the committee's report alleges that the president is exceedingly unpopular among the high school students of the state. Regarding the basis of this charge and the credibility of any testimony to that effect nothing can be said, when nothing is known of the witnesses or their statements. If the truth on this matter is to be ascertained it should be elicited by inquiries from the high schools of the state. It would be most interesting to have high school teachers and their older students, and recent graduates, really express themselves on such a point as this, provided it seems important. The reasons stated by large numbers of the recent freshmen classes of the university when asked to tell why they came to the institution furnished interesting testimony in contradiction of the allegation as made.

It would take too much space to deal adequately with the criticism upon the president for not visiting classrooms. Just a few direct statements may be made. In the first place the board has known, at least since June of 1910, that the president believes any general visiting of university classes by him to be unwise. The board has also known since June of 1910 that the president admits the wisdom of visiting classrooms and laboratories in certain instances and in elementary work. Furthermore the president has visited many laboratories and classes in the university during the last year and a half. An overwhelming majority of college and university presidents do not make a practise of visiting classrooms and declare that such a practise would be unadvisable. Methods that produce good results in the public school system are not applicable to a university faculty composed of highly-trained experts.

It is then declared in general that the president and his policies "seriously retard the growth of the university and impair the usefulness thereof." In the face of the growth

of the university in the last two years, one may fairly call this an amazing statement. In December of 1909 the registration of the university for the current term was 145. In December of 1910 the number had risen to 176. In December of 1911 the number had risen to 191. Let it then be remembered that these are the figures for students of university grade, not including a preparatory department, special music students, or any short-course students—classes which swell the total attendance reported for many institutions. If the unpopularity of the president retards the growth of the university is it not interesting that the last two freshmen classes have been the largest in the history of the institution? If this unpopularity causes the university "to lose many students of the state, and is the reason for many of them going east to school when they should go to the university of their own state," is it not interesting that the same problem of migrating students exists in every western state, and that 21 students have entered the university this semester with advanced standing from other colleges or universities?

The whole tone of the university committee's report presents a curious contrast to the language of the following resolution unanimously adopted by the state board of education on June 6, 1911: "We express our commendation and approval of the highly efficient manner in which he has conducted the affairs of the state university, and express our appreciation of the executive and administrative ability shown by him since he has been president of said institution."

An understanding of the procedure of the state board at its December meeting can be reached only by remembering that the sessions of the board, with its presentation of the committee's report, its discussion of the same, and its action upon it, were held and concluded without conference with the president. The president was in Helena at the time, dealt with the university committee on various matters, attended the open sessions of the board, and informed members of the university committee that he would be in immediate

attendance in the capitol building if his presence were desired for the consideration of any matter affecting himself or the university. He was personally assured that nothing of any importance would come up. After the adjournment of the board, certain of its members told him that no action had been taken, and they made similar statements to reporters, who published their declaration in the newspapers.

All of this leads to the inquiry as to what really happened between June 6, 1911, and October last, when certain very important questions which were up for discussion and settlement during that interval must have seriously changed the relations of the president and members of the board. Since the published statement under consideration does not touch upon these subjects, considerations of official reserve preclude more than this allusion to them at this time.

If I may permit myself now to speak in the first person let me conclude by saying that no one can regret more than myself the necessity of discussing educational matters in this way. Since the board has denied to me the usual academic privilege of meeting them face to face for frank discussion and has chosen to say nothing to me except through newspaper reports I am compelled to follow their example. Only the consideration that the people of the state of Montana need to be informed for the protection of higher education, and of their state university in particular, leads me to address the same public before whom the university committee's report has been placed. I hope that the publicity given to these issues may result in nothing but good for higher education in Montana.—C. A. DUNIWAY, in *The Missoulian*.

SCIENTIFIC BOOKS

The Life of the Crustacea. By W. T. CALMAN, Sc.D. New York, The Macmillan Co. 1911. Pp. xiv + 290, with 32 plates and 85 figures in the text.

While the Crustacea have attracted many generations of able students, and while they possess a truly ponderous and rapidly growing

scientific literature, few attempts have been made at a popular exposition. All the more welcome is the work under review, in which the author, a well-known student and writer in this particular field, presents a sketch of the entire class, as a whole. His expressed purpose is to describe in particular the habits and modes of life, as well as "provide for readers unfamiliar with the technicalities of zoology an account of the more important scientific problems suggested by a study of the living animals in relation to their environment."

Excepting alone the insects, the Crustacea are perhaps the most diversified and the most interesting single class of invertebrates. In their multitudinous forms, whether in the seas, the fresh waters, or upon land, they offer a peculiarly attractive field for the study of nearly every problem raised by modern biology, including development, variation, sex, heredity, parasitism and other phases of evolution. The field is both difficult and alluring. We think that Dr. Calman has succeeded admirably in bringing together a host of significant facts bearing upon his subject, and in presenting them in a logical and interesting manner.

A chapter is devoted to the European lobster, considered as an exponent of the class, and following this are sections on Classification and Metamorphosis. Successive chapters (V.-X.) treat of Crustacea of the Seashore, the Deep Sea, Floating Crustacea of the Ocean, Crustacea of Fresh Waters, the Land, as Parasites and Mesomorphs, all loaded with interesting facts and suggestions. A section devoted to "Crustacea in Relation to Man" is less satisfactory. The volume concludes with a review of Fossil Crustacea. The illustrations are both ample and good.

The author speaks from a wide and accurate knowledge of his subject, and such errors as we have noticed are of a minor character. In the superabundance of available materials, every student of this group is bound to find many omissions of matters more or less interesting or important. In the chapter on the lobster a number of statements need to be

revised in order to accord with our present knowledge of this form. We will note the following: The "liver" is now known to be both a digestive and absorbent organ, the finer particles of food being delivered to it directly from the pyloric end of the stomach-sac. The idea that when a "limb is cast off," the opening at the breaking plane becomes closed by a clot of blood, and that further bleeding is thus stopped, had been proved by Emmel to be an error; the stoppage is effected by definite valves, without which the animal would doubtless bleed to death.

A third species of lobster (*Homarus capensis*) is attributed to the Cape of Good Hope. We were under the impression that this shadowy species had never recovered from the aspersions cast upon it by Professor Huxley. Regarding the relation of the young crayfish to its mother (p. 77) many new facts have been brought to light by the studies of Andrews for both *Astacus* and *Cambarus*.

In discussing the phosphorescence of deep-sea crustacea (p. 126) it is noticed that many luminous forms are blind, but that in such cases luminous secretions are emitted from the skin without the aid of specially differentiated organs, the photophores, the complete meaning of which is puzzling, not to say embarrassing, as in certain prawns which illuminate their gill-chambers. We are reminded of a similar trouble regarding the ubiquitous tegumental glands, which occur among other places in the labrum, swimmerets, statocysts, the intestine and the gills. It might be interesting to inquire whether there is any relation between these organs and such parts of the skin as are responsible for the secretions referred to above. In another place it stated that while many deep-sea species are some tint of red, their eggs are blue or green. If these forms were originally emigrants from shallow water, the colors of the eggs would appear to have remained stable notwithstanding the change in the color and habits of the adult, a condition which is paralleled in certain birds like the magpie, wherein the mottled coloring of the egg is evidently older than the habit of covering the nest.

The author suggests that the exceedingly long, attenuated, and often hirsute character of the appendages of deep-sea crustacea may be an adaptation to prevent the animal from sinking in the ooze; we should rather regard such conditions as aids to the animals for feeling their way in the darkness, in other words, as means for increasing their exploratory powers, and for rendering the chemical sense and that of touch more effective.

Regarding the question of metamorphosis among crustacea of the abyss Dr. Calman remarks: "It would seem that, some way or other, the conditions were unfavorable for a free-swimming larval life; but they can not be altogether prohibitive, for many deep-sea crustacea have small eggs, and presumably a metamorphosis." There is certainly no doubt that such species with small eggs undergo a metamorphosis, but it does not follow that the young ascend a mile or more to the surface in order to accomplish it. Such young may pertain exclusively to the hypoplankton and keep near the bottom, or to the mesoplankton in strata not far above it. It would be interesting to know to what extent larvæ like those of lobsters and crabs which keep for a time at least near the surface, and belong to the epiplankton, can adapt themselves to the changes in pressure involved in falling through measured distances in the water. Experiments to settle this point could be made without great difficulty.

The author thus speaks of the various animals which form the floating population of the Sargassum: "All of them are colored olive-green, like the weed among which they live." Now the Sargassum which we have repeatedly encountered in the Gulf Stream in going to or from the West Indies was always a beautiful golden brown tint, flecked with white, the light spots being due to bryozoa which commonly encrust the floats of this plant. Moreover, the entire population—fish (*Pterophryne*), shrimp and a nudibranch mollusk—wore the same colors, and usually in the same simple pattern, brown with obliterative white spots.

To conclude, in the chapter on the Relation of the Crustacea to Man we miss any adequate account of the valuable lobster fisheries of the old and new worlds, or of the laborious experiments which have been made to rear the young of this much-prized crustacean, and which in America have finally led to success.

FRANCIS H. HERRICK

WESTERN RESERVE UNIVERSITY

Qualitative Chemical Analysis. A Laboratory Guide. By W. W. SCOTT, A.M., chief chemist, Baldwin Locomotive works, formerly Professor of Chemistry, Morningside College, New York. D. Van Nostrand Co. 1910. \$1.50 net.

A Course in Qualitative Chemical Analysis. By CHARLES BASKERVILLE, Ph.D., F.C.S., Professor in the Department of Chemistry of the College of the City of New York, and L. J. CURTMAN, Ph.D., Instructor in the Department of Chemistry of the College of the City of New York. The Macmillan Co. \$1.40 net.

We have in these two books further additions to our already long list of works on qualitative analysis.

The first contains a discussion of the ionic hypothesis, the mass law and other physical chemical principles with their applications to qualitative analysis, followed by a systematic study of the detection and separation of bases and acids, methods of analyzing an unknown substance and tables containing special data. The best methods of separation have been selected and a very valuable addition made in the form of notes on each group. In these notes the reasons for the various reactions used and the precautions recommended are discussed, thus enabling the student to work intelligently and not, as is so often the case, merely mechanically. This book can be recommended as an excellent laboratory guide to qualitative analysis, especially if the principles discussed in the theoretical part are applied to the reactions studied.

In the second work special emphasis is placed on the quantitative discrimination of the substances detected by qualitative meth-

ods of analysis as a preparation for quantitative analysis. In selecting methods of analysis those have been preferably chosen which they think can be most readily used by the student; especially if they give rise to precipitation tests which will enable the student to approximate the amounts present. As in the other work, explanatory notes have been introduced.

An objection the reviewer would make to this book is the almost complete absence of any applications of the present theories of solution and the mass law to the reactions of qualitative analysis. Although the statement is made in the preface that these matters are usually presented in lectures in general chemistry and may be taken up in lectures on qualitative analysis, they do not apply these in this book; but retain the molecular reactions and the theory of the formation of complex compounds in place of the methods which are now so generally taught.

J. E. G.

SPECIAL ARTICLES

CHANGES IN CHEMICAL ENERGY DURING THE DEVELOPMENT OF FUNDULUS HETEROCILITUS

ALTHOUGH at present it is hardly possible to do more than give a brief report of progress, nevertheless, the results which have been obtained from the calorimetric study of the beginning and end stages in the development of *Fundulus heteroclitus* harmonize so completely with the results gotten by Tangl and Farkas in the case of the chick and silkworm, respectively, that a brief account of the work appears warrantable at this time.

Omitting many details of technique, the methods employed in this study were as follows: The eggs of *Fundulus*, immediately after artificial fertilization, and the larvae immediately after hatching, were dried at 40° C. This portion of the work was carried on at the Marine Biological Laboratory at Woods Hole, to whose director, Professor Frank R. Lillie, I am indebted for the use of a room. The material, which had been previously carefully counted, was then preserved in the dry state in ordinary phials until used for the chemical

and calorimetric analyses which were carried out in Budapest.

Determinations of the chemical energy—heat combustion—in known quantities of the material were made by means of the bomb calorimeter, strictly according to the rules of modern calorimetry. Small (practically, between 15° and 25° C.) calories were recorded. Concerning the applicability of thermochemical methods to the study of embryogenesis, nothing need be said at present except that indirectly the work of Rubner and others, while directly that of Tangl and his students, can leave no doubt on this point.

Comparison between the fertilized egg and the hatched embryo of *Fundulus* disclosed a discrepancy in chemical energy which can be in no wise interpreted as an analytical error. Thus briefly summarizing the results, it was found that

	Calories
1,000 fertilized eggs of <i>F. heteroclitus</i> contained	3,264
1,000 hatched larvæ of <i>F. heteroclitus</i> contained	2,550
Transformed during development	710

If loss of energy during development is to have any special significance from the standpoint of embryology, it must be shown that no substances rich in chemical energy diffuse out of the egg during the period under discussion. This seems to be true of *Fundulus*, for the nitrogen content of the egg remains constant up to the 240th hour, and probably for the whole developmental period. In the case of the frog also, no substances appear to diffuse out of the egg, for the ash content remains the same from the beginning of the development to the end. The same thing has also been proved for the trout, the chick and the silkworm (Tangl and Farkas). The only alternative therefore seems to be that the discrepancy in chemical energy between the end and beginning stages of development is due to the transformation of chemical energy into heat, or other forms, and not to the diffusion of energy-containing substances out of the egg.

During the developmental period, 384 hours, during which 1,000 eggs of *F. heteroclitus*

lose 710 calories of chemical energy, larvæ are produced whose organic substance weighs in the neighborhood of 0.2 gram. If now the amount of energy lost is divided by the amount of organic substance produced and multiplied by ten, $710/200 \times 10$, we get 3.6 large (kilogram) calories—an amount which expresses the specific work of development, namely, the amount of chemical energy transformed during the production of one gram of organic substance of *F. heteroclitus*.

The further discussion of these results, as well as of many subordinate questions connected with them, must be reserved for the future, when I shall report upon work of the same kind now in progress on other forms, but not sufficiently advanced to warrant description. The results of Tangl on the chick, however, and of Farkas on the silkworm are highly suggestive, for the specific work of development (Entwicklungsarbeit) of the dry substance (i. e., organic substance + ash) in the case of the former is 3.8 kilogram calories and of the latter 3.1. In consideration of the fact that the errors of observation and analysis are concentrated on these end figures and embodied in them, the almost complete identity of the results for these widely divergent forms,

<i>Fundulus</i>	3.6 ¹ (organic substance)
Chick	3.8 (dry substance)
Silkworm	3.1 (dry substance)

is a strong argument in favor of Tangl's hypothesis expressed two years ago, namely, that the specific work of development (Entwicklungsarbeit) is not a function of phylogenetic position, but the embryogenetic formation of living substances widely divergent in organization seems to be connected with an equal expenditure of chemical energy.

In conclusion, I wish to acknowledge with

¹ Owing to the presence of sea salts in my material, I am unable at this time to calculate the corresponding value for the dry substance of *Fundulus*. Unless the ash diverges very widely from the expected, however, the specific work of development of 1 gr. of dry substance will be in the neighborhood of the value given for the organic substance.

gratitude my great indebtedness to Professor Francis Tangel, director of the Royal Hungarian Institute for Animal Physiology. The unusual generosity with which he placed at my disposal equipment and experience has alone made possible results which otherwise would have been quite beyond my reach.

FOR ANIMAL PHYSIOLOGY,
BUDAPEST, November 20, 1911

THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE
SECTION F

MEETINGS of Section F were held on Wednesday, December 27, the forenoon session for the reading of papers and the afternoon in joint session with the American Psychological Association. The following officers of the section were elected:

Vice-president and Chairman for next meeting—
Professor William A. Lucy.

Member of Council—Professor Edwin Linton.

Member of Sectional Committee for five years—
Professor A. M. Reese.

Member of General Committee—Professor T. W. Galloway.

The following abstracts of papers have been received by the secretary of the section:

REESE, ALBERT M.: *Effect of Narcotics upon the Development of Hen's Egg.*

The paper is a preliminary account of the effect of certain reagents (alcohol, ether, chloroform, chlorotone and magnesium chloride) upon the development of the hen's egg. Alcohol was fatal in about 75 per cent. of the experiments; ether in about 35 per cent.; chloroform, chlorotone and magnesium chloride were almost universally fatal, though the fatalities in the last two cases were probably largely due to faulty technique.

LINTON, EDWIN: (1) *The Adult Stage of Dermocystis stenolabris* Stafford. (2) *Trematode Sporocysts in an Annelid*. (No abstracts of these papers received.)

ROHRER, C. W. G.: *Observations on the Chestnut-worm.*

The chestnut-worm, or grub, is the larval stage of *Balaninus caryatrypes*, one of the Curculionidae or nut-weevils. The "worm" winters in the earth, and issues forth in the spring as a small snout-beetle or weevil. A peck of chestnuts may con-

tain as many as 5,838 worms. One chestnut may contain four or even more. The female, in laying eggs, first bores a hole with her snout through the growing chestnut-burr and into the nut. She then drops an egg into this hole, and pushes it to the bottom of the hole with her snout.

REED, H. D.: *The Occurrence of Dermal Poison Glands in the Nematognathi*. (No abstract received.)

SMITH, HUGH M.: *Notice of a Remarkable New Family of Pediculate Fishes.*

Among the fishes collected by the *Albatross* during the 1907-1910 expedition to the Philippine Islands is a deep-water pediculate from the coast of Celebes, which becomes the type of a new species, genus and family.

ROGERS, BURTON R.: *A New Method of Preserving Anatomical Dissecting Material of Large Animals*. (No abstract received.)

SMITH, MIDDLETON: *The Bowhead*.

Description of the whale; of the primitive implements used in its capture; of the method of killing and "cutting in" as practised by the Eskimo; and of the uses of its products.

CLARK, AUSTIN H.: *A Biological Contribution to the Paleogeography of Australia*.

The old continent of Australia included the present Australia, with New Guinea and the Aru Islands to the north and Tasmania to the south. Timor, Timorlaut, the Ki Islands, Ceram, Gilolo and the islands further west, the islands north of New Guinea, New Britain, New Caledonia, Norfolk Island, New Zealand and the islands further north and east have no relationship whatever with Australia, but form part of more or less marked subdivisions of the East Indian region.

The Australian coast line has subsided since the maturity of the true Australian erinoid fauna; this subsidence has been least on the southeast coast, the degree gradually increasing toward the west and with slightly greater rapidity toward the north; on the west coast there is a similar increase in the degree of submergence from the south to the north. The Australian erinoid fauna of to-day is in the midst of one of those faunal changes called by Cuvier a "cataclysm."

JOHNSON, M. E., and TORREY, H. B.: *Control of Color Differentiation in Frog Tadpoles*.

Experiments have shown that the amount of melanin developed in the skin of frog tadpoles varies with the kind rather than with the quantity of food. Among tadpoles growing at the same

rate, those fed on beef liver produced more melanin than those fed on egg yolk. Egg albumen, beef suet and brown beans resembled beef liver in this respect. These results point directly to the presence of substances in the food that exert a specific influence upon melanin formation. It is well known that tyrosin may be oxidized to melanin in the presence of tyrosinase in various organisms. In the experiments, any possible tyrosinase in the food was inactivated by boiling the latter; and tyrosin was present in excess in the tissues. These facts suggest the presence of an inhibitor in the egg yolk, an idea supported by numerous experiments in glass. Tyrosin + tyrosinase + egg yolk (digested or undigested) produce little or no color, while tyrosin + tyrosinase + beef liver (digested or undigested) together produce a marked reaction. That the inhibiting factor may exist in the fat content of the food (i. e., lecithin, cholesterol) is a possibility now under investigation.

WOODRUFF, L. L.: *Observations on the Origin and Sequence of the Protozoan Fauna of Hay Infusions.*

Data derived from the daily observation, for several months, of the sequence of various types of protozoa in a large number of infusions of hay. Attempt to show that there is a more or less regular sequence. Data also on the source of the protozoa observed in infusion.

MACCURDY, H. M.: *Observations on the Reactions of Asterias forbesii to Light.*

Specimens from six to twelve centimeters in diameter respond definitely and are negative in their reactions to sunlight. The first visible effect of light is a characteristic ventralward movement of the affected rays or ray, accompanied by a retraction of the tube feet. This reflex takes place in specimens either with or without the eye spots. The so-called eyes are drawn inward and the surrounding spines close more or less closely over them in bright light, and the tips of the exposed rays are held low. These reflexes may be local or general. They tend to inhibit or counteract exploratory movements, retard current impulses and induce physiological states and relations which require readjustment. The direction of the new movements is influenced by the retarding effect of light and is determined by impulses from the central nervous system. The tube feet extend readily in shade, and toward the shaded side of a ray. Light retards extension movements. The same is true for the tube feet of *Cribrella sanguinolenta* and *Thyone briarius*. It thus appears

that the tube feet as well as the surface of the rays are sensitive to light. The outcome of the reaction is a succession of events usually though not invariably the result of the checking of some movements and the freedom of others. A movement becoming effective functionally induces co-operation in adjacent parts not in that condition. A contact stimulus is functionally stronger than the light stimulus, but is influenced by the latter.

GUDGER, E. W.: *Oral Gestation in the Gaff-topsail Cat-fish, Felichthys felis.*

How the eggs are extruded, fertilized and transferred is not known, but when these processes are effected the male incubates them in his mouth not only until they are hatched by the bursting of the shell, but until the yolk has been absorbed and the young are able to care for themselves. The largest number of eggs taken from the mouth of one male was 55. A cement cast of his mouth had a volume of 580 c.c. The volume of an average-sized egg is 3.75 c.c., of the 55 eggs 206.3 c.c., add 25 per cent. for interstices; total space occupied by the 55 eggs equals 258 c.c. This fish was 22 inches long, and of average size. The eggs average 19-20 mm. in diameter, and the young fish at the end of the period of incubation are 85-100 mm. long. The length of this period can not be stated definitely, since it has been found to be impossible artificially to carry the eggs and embryos to the stage of the free-swimming young. However, it is about 80 days. During all this time the nurse does not seem to feed. The large eggs would, if spawned on sandy or shelly bottoms, be quickly destroyed by crabs and by other fish; if laid on a mud bottom (where the breeding fish are caught) their considerable weight would cause them to sink into and be smothered by the mud. The habit is common to estuarine cat-fish in all tropical and warm temperate regions. These data are based on five summers' work at the Beaufort Laboratory of the United States Bureau of Fisheries, in which time scores of male fish carrying eggs and larvae have been captured and autopsied.

PARKER, G. H.: *The Nervous and Non-nervous Reactions of Actinians.* (No abstract received.)

MAST, S. O.: (1) *The Behavior of Fireflies and its Bearing on Certain Theories of Tropisms.* (2) *Seventeen Different Definitions of the Term Tropism as Applied to Reactions in Organisms.* (No abstract received.)

ESTERLY, C. O.: *The "Oil Fly" of California, Psilopa petrolei.*

The larvæ live in crude oil in incredible numbers. The eggs seem to be deposited outside the oil and the larvæ enter the oil as soon as they hatch. The maggots float in the oil whether it is of the heaviest or lightest specific gravity. All the crude oils observed are lighter than water, but the larvæ sink in water. Even when the animals are motionless in crude oil, they remain on the surface with only the breathing tube visible. If the larvæ are put into such products of petroleum as distillate or kerosene, or such substances as olive oil, they live for from 24 to 48 hours. They do not float in these fluids and it seems likely that the chemical nature of the substances is not the only unfavorable condition. The maggots swarm about the bodies of animals like moths or caterpillars caught in the oil and doubtless feed on them. Yet if the larvæ are kept in oil taken direct from the pump or in that filtered through asbestos, they seem to do equally as well, even to pupating. It seems unlikely that organic particles could be present in such oil, and it is an interesting problem whether the animals can obtain nutriment directly from petroleum. Pupation takes place very readily in the laboratory. The proportion of pupæ formed from larvæ kept in fresh pumped or filtered oil is as large as that in oil taken from pools around tanks or wells. The adults and larvæ do not seem to be phototropic, yet the pupæ have temporary positive phototropism. The paper included a description of larval movements.

MAURICE A. BIGELOW,
Secretary of Section F

THE AMERICAN PHYSIOLOGICAL SOCIETY

THE twenty-fourth annual meeting was held in Baltimore and Washington, December 26-29, 1911. Two business sessions and five scientific sessions were held in Baltimore. Two of the scientific sessions were joint meetings with the Biochemical and the Pharmaceutical Societies.

An unusual number of papers and demonstrations—in all sixty-seven—were presented and discussed, and the sessions were well attended, eighty-six of the society's one hundred and ninety members being present at the meeting.

At the first session in Baltimore President Meltzer made a brief and appropriate reference to the late Professor H. P. Bowditch, one of the founders of the society, at the conclusion of which the members present arose and remained standing for one minute as a token of respect to the memory of Dr. Bowditch. This was followed by the

reading of a memorial address on Professor Bowditch by W. B. Cannon.

The following papers and demonstrations were presented at the Baltimore sessions:

W. W. Osterhaut: The Effect of Anesthetics on Protoplasmic Permeability.

F. S. Lee and A. M. Guenther: Some of the General Physiological Properties of Diaphragm Muscle.

J. Auer: The Action of the Digitalis Group upon the Heart and its Similarity to Cardiac Anaphylaxis.

P. E. Howe (by invitation) and P. B. Hawk: A Comparison of the Data from Two Fastings Each Exceeding One Hundred Days in Length and made upon the same Subject.

J. Erlanger: Observations on the Physiology of Purkinje Tissue.

W. B. Howell: Antithrombin.

W. J. Meek: Relation of the Liver to Fibrinogen Formation.

Th. Hough: The Influence of Different Degrees of Muscular Activity on the Alveolar Tension of Oxygen and Carbon Dioxid.

Y. Henderson: A Brief Report upon the Pikes Peak Expedition.

A. S. Loevenhart: A Contribution to the Theory of the Respiration.

W. T. Porter: The Vaso-motor Nerves of the Heart.

W. T. Porter: Remarks on the Relation of the Phrenic Nerve to the Spinal Respiratory Cells.

T. S. Githens and S. J. Meltzer: The Effect of the Removal of the Heart upon Morphinized Frogs.

T. Sollmann and P. J. Hanzel (by invitation): Post-mortem Absorption by the Lymph Vessels.

Y. Henderson: Some New Respiration Apparatus.

W. Salant: A Modified Langendorff Apparatus for Perfusion of Isolated Heart.

G. W. Fitz: A Perfected Model of the Shadow Pupilometer.

W. T. Porter: An Improved Membrane Manometer.

A. J. Carlson: A Method for Studying the Movements and Tonus of the Empty Digestive Tract by the Means of the X-ray.

C. C. Guthrie: Some New Apparatus.

H. Cushing: The Hemodynamic Action of the Cerebrospinal Fluid.

F. S. Lee and M. Levine: The Action of Alcohol and Water on Muscle.

J. Auer and S. J. Meltzer: (1) The Respiratory Effect of Electrical Stimulation of the Central End of the Vagus Nerves in Dogs. (2) Inhibition of Respiration by Distention of the Lungs of Dogs under Intratracheal Insufflation.

C. Brooks: The Action of Sodium Citrate on the Circulation.

C. W. Greene: The Absorption of Fat by the Salmon Stomach.

C. W. Greene and Mr. Skaer: The Absorption of Fat by the Mammalian Stomach. (Preliminary communication.)

H. McGuigan and O. Mostrom: Studies on the Convulsive Reflex Produced by Strychnine, (a) Habit, (b) As Modified by Epinephrine.

W. E. Garrey: Temperature Coefficient of Nerve Cells of the Ganglionated Cord of Limulus Heart.

The program for the joint session with Section K, American Association for the Advancement of Science, in Washington, consisted of a symposium on Acapnia and Shock. Papers were presented by Y. Henderson, W. H. Howell, G. W. Crile, J.

Erlanger and S. J. Meltzer. The general discussion was participated in by W. T. Porter, J. J. R. Macleod, G. W. Crile, A. J. Carlson, G. T. Kemp and Y. Henderson.

The following persons were elected to membership in the society:

Rockefeller Institute—A. E. Cohn, I. S. Kleiner, F. W. Bancroft.

Johns Hopkins University—L. G. Rowntree, G. H. Whipple, W. E. Burge.

University of Pennsylvania—R. M. Pearce, A. I. Ringer.

University of Syracuse—F. P. Knowlton, C. G. Rogers.

Columbia University—H. A. Stewart.

University of Nebraska—A. E. Guenther.

University of Wisconsin—H. C. Bradley.

University of California—T. C. Burnett.

Western Reserve University—P. W. Cabb.

Starling-Ohio Medical School—R. G. Hoskins.

University of Chicago—A. B. Luckhardt.

The relation of the society to the *American Journal of Physiology* continues as in the past, and A. J. Carlson, W. H. Howell, F. S. Lee, G. Lusk, S. J. Meltzer and W. T. Porter were appointed to constitute the editorial committee for the publication of the *Journal* during 1912.

In the past the annual meeting of the society has occupied three days of the convocation week. But owing to the rapidly increasing number of workers in the society the number of papers submitted for the meetings has already become too great for proper presentation and discussion, in spite of the recent organization of the Biochemical and the Pharmacological Societies. It is generally felt that much of the value of these meetings is lost when time is lacking for adequate discussion of the scientific program. At the second business session this question was considered and the following measures in the way of remedy were proposed and discussed:

1. Extending the time of the meeting to four or more days.

2. Meeting in two or more sections according to subjects.

3. Two or more meetings annually—one in the west and one or more in the east.

4. Limiting the number of papers (each member is at present virtually limited to one communication).

5. Dispense with the formal reading of papers, and devote the time to their discussion on the basis of printed abstract.

6. Changing the time of the meeting to May or June.

7. A closer affiliation with the Biochemical and the Pharmacological Societies.

After a prolonged and earnest discussion the question was referred to the council with instructions to report at the next annual meeting, which will be held in Cleveland, Ohio, in December, 1912.

The following officers were elected for the year 1912:

President—S. J. Meltzer, New York.

Secretary—A. J. Carlson, Chicago.

Treasurer—W. B. Cannon, Boston.

Members of the Council—J. Erlanger, St. Louis, and F. S. Lee, New York.

The arrangements effected by the Baltimore members and friends of the society contributed greatly to the success of the meeting. The headquarters of the three societies were located in the same hotel, and practically all the visiting members were housed in this same hotel. The local members had agreed to dispense with private entertainments, and in their place had arranged for all members and visiting friends an informal dinner followed by a smoker on the evenings of December 27 and 28. By this delightful informality the members were kept together and opportunities afforded for social intercourse and informal conferences and discussions. It was generally felt that this feature should be perpetuated in future meetings.

A. J. CARLSON,

Secretary

UNIVERSITY OF CHICAGO,
January, 1912

THE AMERICAN SOCIETY OF BIOLOGICAL CHEMISTS

THE sixth annual meeting of the American Society of Biological Chemists was held in Baltimore and Washington, December 27-29, 1911. The sessions in Baltimore, held in affiliation with the American Physiological Society and the American Society of Pharmacology and Experimental Therapeutics, in the physiological building of the Johns Hopkins Medical School, were well attended, over forty of the members being present.

The single session in Washington, at the McKinley High School, a joint meeting with the Biological Section of the American Chemical Society, was of exceptional interest from the standpoint of the character of the papers presented and the discussions which they elicited. The following

is a list of the communications which were offered at these meetings:

BALTIMORE, WEDNESDAY, DECEMBER 27, 2:00 P.M.

W. R. Blatherwick, C. P. Sherwin and P. B. Hawk: Intestinal Putrefaction and Bacterial Development accompanying Water Drinking and Fasting.

Amos W. Peters: Essential Conditions of Accuracy and Rapidity for the Determination of Sugar by the Methods of Copper Reduction.

S. R. Benedict: Preparation of Creatine and Creatinine from Urine.

S. R. Benedict: Estimation of Creatinine.

H. S. Raper: The Fate of Fat which Enters the Blood Stream.

H. Gideon Wells: Purines and Purine Enzymes of Tumors.

Fletcher McPhedron: Hemolytic Power of Fatty Acids.

P. A. Shaffer: A New Salt of β -Oxybutyric Acid.

Lawrence T. Fairhall and P. B. Hawk: The Allantoin Output of Man after Water Ingestion.

The following papers were read by title:

E. B. Hart, E. V. McCollum and H. Steenbock: Physiological Effects on Growth and Reproduction of Rations Balanced from Restricted Sources.

E. V. McCollum and J. G. Halpin: Synthesis of Lecithins in the Hen.

E. B. Hart and H. Steenbock: Effect of High Magnesium Intake on Calcium Excretion by Pigs.

E. V. McCollum: Relation between Nitrogen Retention and the Rise of Creatinine Excreted during the Growth of the Pig.

E. V. McCollum: Comparison of the Nutritive Value for Growing Pigs of the Nitrogen from the Oat and Wheat Grains.

E. V. McCollum and E. B. Hart: Experiments on Feeding Dissected Milks.

BALTIMORE, THURSDAY, DECEMBER 28, 9:00 A.M.

(Joint session with the American Physiological Society)

J. R. Murlin and H. C. Bailey: The Urine of Late Pregnancy and the Puerperium.

C. W. Greene: The Storage of Fat in the Salmon Muscle Tissue and its Resorption during the Migration Fast.

H. C. Bradley and H. S. Gasser: Intestinal Absorption.

J. J. R. Macleod: The Relationship of the Suprarenal Glands to Sugar Production by the Liver.

Victor C. Meyers and G. O. Volovic: Metabolism in an Experimental Fever with Special Reference to Creatinine Elimination.

Thomas B. Osborne and Lafayette B. Mendel: The Role of Proteins in Growth.

A. B. Macallum: The Role of Surface Tension in the Distribution of Salts in Living Matter.

I. S. Kleiner and S. J. Meltzer: A Comparison of the Effects of Subcutaneous and Intravenous Injections of Adrenalin upon the Production of Glycosuria.

H. B. Williams, J. A. Riche and Graham Lusk: The Hourly Chemical and Energy Transformations in the Dog which Follow the Ingestion of Meat.

Andrew Hunter and Sutherland Simpson: The Iodine Content of Thyroid Glands of Sheep Fed Mainly upon Marine Algae.

Edward B. Meigs and L. A. Ryan: The Chemical Constituents of the Ash of Smooth Muscle.

BALTIMORE, THURSDAY, DECEMBER 28, 2:00 P.M.

H. H. Bunzel: Measurements of Oxidases.

J. R. Murlin and H. I. Muller: Creatine Elimination in the Pregnant Dog.

J. J. R. Macleod, C. D. Christie and J. D. Donaldson: The Estimation of Dextrose in Blood and Urine by the Difference in Reducing Power before and after Yeast Fermentation.

Torald Sollman (for P. J. Hanzlik): Recovery of Alcohol from Animal Tissues.

Otto Folin and F. F. Flanders: A New Method for the Determination of Hippuric Acid (and Benzoic Acid) in Urine.

H. C. Bradley: Synthetic Action of Enzymes.

Paul E. Howe and P. B. Hawk: A Metabolism Study on a Fasting Man.

Paul E. Howe and P. B. Hawk: Hydrogen Ion Concentration of the Peces.

The following papers were read by title:

H. C. Jackson: Changes in the Composition of Blood and Muscle following Double Nephrectomy and Bilateral Ureteral Ligation.

C. C. Benson: Note on the Inorganic Constituents of Human Blood.

P. A. Levene and W. A. Jacobs: On Sphingosin.

P. A. Levene and G. M. Meyer: On Glycolysis.

P. A. Levene and D. D. Van Slyke: On the Pterates of Glycocol.

H. C. Bradley: Connective Tissues of *Limulus*.

C. F. Langworthy and R. D. Milner: The Respiration Calorimeter and its Uses for the Study of Problems of Vegetable Physiology.

H. McGuigan and C. L. von Hess: Glycolysis as Modified by Removal of the Pancreas and by the Addition of Antiseptics.

H. McGuigan: On the Excretion of Formaldehyde, Ammonia and Hexamethylenamine.

A. D. Emmett: Effect of the Quantity of Protein Ingested on the Nutrition of Animals. VI. On the Chemical Composition of the Entire Body of Swine.

O. H. Brown: The Effect of Quinine on Pneumococci.

WASHINGTON, FRIDAY, DECEMBER 29, 2:30 P.M.
(Joint session with the Biological Section of the American Chemical Society)

Thomas B. Osborne and Lafayette B. Mendel: Maintenance and Growth.

Wilder D. Bancroft: The Study of Environment.

Treat B. Johnson: Synthesis of Thiotyrosine.

Alfred Dachnowski: The Relation of Vegetation to the Chemical Nature of Peat Soils.

C. L. Alsberg and O. F. Black: Phytochemical Studies on Hydrocyanic Acid.

Andrew Hunter and M. H. Givens: The Nitrogen Excretion of the Monkey with Special Reference to the Metabolism of Purines.

John H. Long: The Definition of Normal Urine.

W. Koch: Should the Term Protagon be Retained?

H. S. Reed and H. S. Stahl: Oxidizing Enzymes in Certain Fungi Pathogenic for Plants.

William J. Gies: Modified Collodion Membranes for Studies of Diffusion.

M. S. Fine: A Method for Differentiating between Metabolic and Residual Food Nitrogen in the Feces.

E. Monroe Bailey: Biochemical and Bacteriological Studies on the Banana.

The following officers were elected for the year 1912:

President—A. B. Macallum.

Vice-president—Graham Lusk.

Secretary—A. N. Richards.

Treasurer—Walter Jones.

Additional Members of Council—H. P. Armsby, Lafayette B. Mendel, H. Gideon Wells.

Nominating Committee—John J. Abel, F. G. Benedict, H. C. Bradley, Otto Folin, Wm. J. Gies, Andrew Hunter, J. B. Leathes, J. J. R. Macleod, D. D. Van Slyke.

A special committee, consisting of W. Koch (chairman), H. D. Dakin, William J. Gies, J. B. Leathes and Jacques Loeb, was appointed for the

purpose of considering and reporting to the society concerning the nomenclature of the lipoids.

Resolutions were passed by the society concerning the recent deaths of three of its members, Dr. Raymond H. Pond, Dr. Arthur H. Koelker and Professor William F. Koelker.

A. N. RICHARDS,
Secretary

THE MEETINGS OF THE ECONOMIC AND SOCIOLOGICAL SOCIETIES AT WASHINGTON

SEVEN societies met at Washington during the holidays to discuss economic and sociological problems. These societies represent the various fields of economics, civics, home economics, labor, sociology and statistics. Acting under the rule of the council of the American Association for the Advancement of Science adopted at Minneapolis, Section I, devoted to economics and social science, yielded the regular program to the visiting societies with the exception of two sessions, provided by the management governing the correlation of the sections to visiting societies.

One of the notable features of the convocation was the address of Senator Burton, the retiring vice-president of Section I, delivered at a joint session of the American Civic Alliance and of the section at which Dr. J. Pease Norton presided. The address of Senator Burton on the "Causes of the High Prices" has been printed in full in *SCIENCE*. Senator Burton presented an analysis of the causes which have operated to increase prices and showed conclusively that in addition to the vast increase in the gold supply many individual causes have been operative. The American Economic Association adopted a resolution in favor of an International Commission on the Cost of Living to study the remedies. This was the subject of a round table discussion led by Professor Fisher. Senator Burton's opinion was that natural causes would in a short time produce relief.

At this session the section adopted this resolution:

"*Resolved*: That the chairman be empowered to appoint a committee whose power and duty shall be to take such steps as shall in its opinion be most effective in focusing the attention of the proper persons and institutions upon the problems of soil erosion and the improved utilization of land through tree crops. This committee to report at the next meeting of the association."

Other addresses were delivered at this meeting

on "Review and Outlook for Banking Reform" as follows:

1. "Requirements of the South in Banking Reform," by William A. Blair, vice-president of the People's National Bank, Winston-Salem, N. C.

2. "The Function of a Gold Reserve in a National Banking System," by Hon. George E. Roberts, Director of the Mint, Washington, D. C.

3. "Relation of Banking Reform to Corporate Financing," by Mr. J. Selwyn Tait, late manager of the International Banking Corporation's Branch, Washington, D. C.

4. "The United States Treasury as Related to the Country's Banking System," by the Hon. Lee McClung, Treasurer of the United States.

5. General discussion of foregoing papers, by Roger W. Babson, formerly expert for the Monetary Commission, Wellesley Hills, Mass.

The Friday evening session of the section, to which the members of the American Economic Association and those of the American Civic Alliance were invited, was one of the largest meetings of the series. Some seven hundred persons listened to addresses on "Corporate Problems of To-day." Dr. John Franklin Crowell, associate editor of the *Wall Street Journal*, was in the chair and opened the session with a brief address. Six speakers summarized the corporate problems of banking and currency, of the railroads and of the industries. The program was:

1. "Problems of Banking and Currency," (a) by the Hon. A. Piatt Andrew, assistant secretary of the Treasury, Washington, D. C.; (b) by the Hon. James T. McCleary, secretary of the American Iron and Steel Institute, New York City.

2. "Problems of Industrial Corporations," (a) by Professor T. N. Carver, of Harvard University, secretary of the American Economic Association; (b) by Hon. John Hays Hammond, Washington, D. C., late special ambassador of the United States to Great Britain.

3. "Problems of Railway Corporations," (a) by John B. Daish, Esq., counselor-at-law, Washington, D. C.; (b) by Samuel Untermyer, Esq., counselor-at-law, New York City.

Each paper presented in succinct form the essential limitations of the problems. If the six addresses were printed together, an excellent handbook of the corporate problems of to-day would be furnished for students of this field.

Much interest was aroused by the address of Mr. John Hays Hammond, relating to the Industrial Corporations, in which he advocated a federal commission. At the close of the meeting, Dr.

Crowell announced the election of Mr. John Hays Hammond to the vice-presidency of the section, succeeding Dr. J. Pease Norton.

Smaller meetings and round table gatherings were held by the visiting societies. The Home Economics Society presented a large and varied program.

The American Economic Association discussed immigration, economic concepts, tariff investigations and the decline of rural population in the south. In the session on tariff legislation Professor H. Parker Willis took issue with Professor Henry C. Emery in regard to the principles underlying the investigations of the Tariff Board and the result was an illuminating discussion fruitful of results.

Dr. John L. Coulter, of the University of Minnesota, and Dr. Frissell, principal of Hampton Institute, spoke on "Rural Conditions in the South."

An important symposium of the American Civic Alliance on the subject of "Old Age Retirement" was participated in by several speakers. Mr. Miles Dawson, actuary of the Armstrong Commission, discussed retirement plans in foreign countries and showed the necessity of the straight pension plan. In this opinion Mr. Dawson was seconded by Mr. M. F. O'Donoghue, president of the United States Civic Service Retirement Association, representing a quarter of a million government employees. An opposite view was taken by Congressman Gillette, who advocated that a portion of each employee's salary or wages be reserved by the government for the use of the employee after his retirement, this fund to be free from attachment and alienation. This plan, sometimes called the "Compulsory Savings Plan," was put forward as the remedy for the situation developed by the large number of superannuated employees in the civil service.

Interesting sessions were held by the statisticians. "The Naturalization of Immigrants" from a statistical standpoint was presented by Mr. Fred C. Croxton, statistician of the U. S. Immigration Commission. Other sessions were devoted to the "Forecasting of Business Conditions by a Study of Statistics" and "Industrial Injuries." The former was treated by Mr. Roger W. Babson, economic engineer, of Wellesley Hills, Mass., and by Dr. John F. Crowell, of the *Wall Street Journal*. The latter was discussed in a joint session of the Statisticians and the American Association for Labor Legislation, led by Charles P. Neill, Commissioner U. S. Bureau of Labor; Frederick L. Hoffman, president of the Statistical

Association; Mr. David Van Shaack, of the Ætna Life Insurance Company, and others. The Association for Labor Legislation also held an important meeting on Friday afternoon on "The Unemployment Problem in America." Secretary Nagel presided.

The only criticism that could be made is that there were too many important meetings held at substantially the same time, so that it was impossible to attend them all. The general result was that one attended that meeting wherein his own personal interest lay, and thus lost the opportunity of hearing and knowing about other subjects, which frequently throw a side light previously unnoticed on one's own ideas and viewpoint.

SEYMOUR C. LOOMIS

SOCIETIES AND ACADEMIES

THE AMERICAN PHILOSOPHICAL SOCIETY

At the meeting of the American Philosophical Society, at Philadelphia, on January 5, 1912, Professor D. W. Johnson, of Harvard University, presented a paper on "The Physical History of the Grand Canyon District."

Few points of geological interest appeal so strongly to the public as the Grand Canyon of the Colorado River. Both in the Canyon itself and in the adjacent plateaus, the geological structure most profoundly affects the scenery. The scenic features may be best appreciated if we know the succession of events in the physical history of the region which are responsible for the present surface forms. This succession was made clear by means of a series of diagrams representing various stages in the development of the district. It was shown that the ancient crystallines of the Granite Gorge, the inclined beds of the Algonkian wedge, and the horizontal strata of the Plateau series, as well as the great erosion surfaces which separate these groups of rocks, have all played a part in determining the character of the Canyon scenery; while the Plateau scenery has been profoundly affected by the north-south folds and fractures, vulcanism and long-continued erosion periods. This relation of geology to topography was shown by colored lantern views of the principal features of the district. On the basis of these views a more detailed analysis of certain events in the geologic history was presented.

THE BOTANICAL SOCIETY OF WASHINGTON

The 77th regular meeting of the society was held at the Cosmos Club, Tuesday, January 9,

1912, at eight o'clock P.M. President W. A. Orton presided. Twenty-six members and ten guests were present. E. O. Wootton and F. D. Farrell were admitted to membership.

The following papers were read:

Botanical Gardens of the East: Lyster H. Dewey.

The author made a trip to Java to attend the International Fiber Congress and Exhibition held at Soerabaya in July, 1911, and visited *en route* the botanical gardens in Gibraltar, Algiers, Penang, Singapore, Buitenzorg, Hongkong and Taihoku, Taiwan (Formosa). After describing these gardens in detail the author stated that they are fulfilling a many-sided mission in attracting tourists, educating even the casual observer as to the identity of plants, indicating the sources of plant products, introducing and distributing plants of economic value and affording research workers exceptional opportunities for study.

Fermentation of Cellulose: K. F. Kellerman, I. G. McBeth and F. M. Scales. (Presented by Mr. Kellerman.)

In the formation and maintenance of humus in agricultural soils the fermentation of cellulose is probably of fundamental importance, yet our knowledge of this question is inadequate. Omeliansky's generally accepted conclusions that cellulose is destroyed only under anaerobic conditions and gives rise either to hydrogen or to methane are erroneous.

Two species of cellulose-destroying and five species of contaminating bacteria were isolated from a culture of Omeliansky's hydrogen organism, and one cellulose-destroying and two contaminating forms from his methane culture; none of the three fermenting species showed any resemblance to Omeliansky's hydrogen or methane ferments. In addition to the species isolated from Omeliansky's cultures eleven other species have been isolated from various other sources; one isolated from manure belongs to the thermophile group.

Contrary to Omeliansky's observation that cellulose-destroying bacteria do not grow upon solid media, most of the species isolated were found to grow readily upon such media as beef agar, gelatin, starch and potato. Some are facultatively anaerobic, but none are strictly anaerobic.

It is usually supposed that filamentous fungi are of little importance in agricultural soils; these investigations show them to be at least as impor-

tant as bacteria in destroying cellulose. About seventy-five species of molds have been isolated, representing a large number of genera; species of *Penicillium*, *Aspergillus* and *Fusarium* are perhaps most numerous.

In the destruction of pure cellulose, either by bacteria or molds in synthetic media, the associative action of organisms which presumably have no cellulose-dissolving enzymes frequently stimulates the growth of the cellulose organism and increases its destructive power.

Some Phases of Microscopical Detection of Decomposition in Food Products: B. J. HOWARD.

W. W. STOCKBERGER,
Corresponding Secretary

THE TORREY BOTANICAL CLUB

THE meeting of November 14, 1911, was held at the American Museum of Natural History at 8:15 P.M., Vice-president Barnhart presiding. Forty-five persons were present.

The minutes of the meetings of October 10 and October 25 were read and approved.

Mrs. N. C. Nuris, 611 W. 177th St., New York City, and Dr. George F. Bovard, University of Southern California, Los Angeles, Cal., were proposed for membership. There being no further business to consider, Mrs. N. C. Nuris was then elected to membership in the club.

The announced scientific program of the evening consisted of a lecture on "Trees of New York City," by Professor C. C. Curtis. The lecture was illustrated by numerous lantern slides.

B. O. DODGE,
Secretary

THE meeting of November 29, 1911, was held in the laboratory of the New York Botanical Garden and was called to order at 3:40 P.M. by the acting secretary in the absence of other officers. The reading of minutes and the transaction of business were passed over and the meeting proceeded with the scientific program. The first announced paper was by Mr. Arlow Burdette Stout on "The Characteristics of the Fungus *Sclerotium rhizodes*, with special reference to its Action on the Cells of its Host," of which the following is an abstract:

Mr. A. B. Stout presented in part the results of his investigations of the fungus *Sclerotium rhizodes* Auerw., a complete report of which will soon appear in a research bulletin of the Wisconsin Agricultural Experiment Station.¹

Special mention was made of the behavior of the fungus in the different organs of the host plant and microscopical preparations were exhibited demonstrating the relations of the fungus to the cells of its principal host *Calamagrostis canadensis*.

The fungus is coexistent in leaves, buds, stems, rhizomes and roots of the infected plants. Filaments of the fungus also form a thin weft on the exterior of the roots and extend out into the soil.

In the leaves the fungus is vigorously parasitic. In the culms fungal filaments are most abundant in the region of the nodes, but there is almost no destruction of tissues. In the underground parts of the culms, and in rhizomes the hyphae completely digest the cell contents of cortical cells, but have no effect on the cell walls except at the points of actual penetration. In the older portions of roots the hyphae are scattered through the cortex, where they occupy empty cells. In the younger lateral roots the filaments of the fungus are found penetrating living cells and exhibiting characteristics which have been ascribed to mycorrhizal fungi. Ultimately, however, the cell contents disappear while the fungus remains intact.

The fungus is perennial in the soil, and in the underground portions of the host. It is present in buds, but is unable to penetrate into the growing apex.

The fungus, therefore, exhibits a varying degree of parasitism in the different parts of the host.

The presentation of the second announced paper, "Studies on the Growth and Reproduction of certain Species of *Ascobolus*," by Mr. Bernard O. Dodge, was omitted on account of the illness and absence of Mr. Dodge.

Mrs. N. L. Britton exhibited drawings and microscopic preparations illustrating certain types of thickening in the cell walls of the leaves of mosses.

Dr. N. L. Britton discussed the characters of a new species of *Elaeagia* from Cuba. This is a Rubiaceae shrub 8 or 10 feet high, with fruit imperfectly known. The hitherto known species of the genus *Elaeagia* occur in the Andes of South America and this new plant from the mountains of Cuba forms another link in the chain of relationship between the flora of the higher altitudes of the West Indies and that of the mountains of South America.

MARSHALL A. HOWE,
Secretary pro tem.

¹ A more complete abstract than is here given appeared in *Phytopathology*, I., 69.

THE historian of the future will probably characterize the period upon which we are now entering in psychology as the period of the rise of the applied psychological sciences. It may, therefore, be meet and proper to take some fundamental concept of applied psychology as topic for this annual address. I select for this purpose the rôle of mental measurement—the possibility, the scope and the meaning of mental measurements as the foundation of applied mental sciences.

In order to illustrate the scope and significance of mental measurement in a concrete and specific instance, I shall make bold to present a psychological outline of the measurement of an individual as a singer. Let us make the assumption that this individual is a girl, fifteen years of age, who has had musical training and now desires the best obtainable advice from a consulting psychologist in music in regard to her future prospects as a singer.

Musical power is generally admitted to embrace certain well-recognized and fairly concrete capacities. In our commonplace judgment about ourselves and others we say: "I have no ear for music." "I can not tell a chord from a discord." "I can not keep time." "I have no sense of rhythm." "I can not tell a two-step from a waltz." "I can not remember music." "I can not image sounds." "I am not moved by music." "I do not enjoy music." Or, if speaking of some one who has musical ability, we say: "He has a

¹MSR, intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹The annual address before the American Psychological Association, Washington, D. C., December, 1911.

deep rich voice." "He never forgets an air." "He lives in song." Such judgments have reference to generally admitted specific factors involved in musical capacity by virtue of a musical organization. Corresponding to these judgments of native capacity we have judgments about musical education, about musical environment, about special influences and stimuli for the development of musical talent, and about technique and success in the rendition of music. When judgments of this kind are based upon measurements, classified, and adequately interpreted, they may constitute a measure of the individual as a singer.

Unfortunately, we have not the command of an expert in the psychology of music, and the field before us is practically unworked. The illustration will, therefore, be merely a tentative suggestion to blaze the trail a little way.

The measure of a singer should consist of a relatively small number of representative measurements upon specific capacities and achievements. These measurements must be set in a full survey by systematic observation and other verified information bearing upon the valuation of the individual as a singer.

The classification of the measurements must be based upon (1) the attributes of sound which constitute the objective aspect of music, and (2) upon fundamental and essential processes in the singer's appreciation and expression of music.

From the point of view of the objective sound, we must take into account pitch (with its complexes of timbre and harmony), intensity and duration.² From the point of view of mental processes, we may group the tests under the heads, sensory,

motor, associational, and affective, each of these furnishing natural subdivisions. The measurements may thus be arranged in the following program, which should also be the outline for a systematic description.

LIST OF MEASUREMENTS ON A SINGER

I. Sensory.

A. Pitch.

1. Discrimination at a' , 435 vd.
2. Survey of register of discrimination.
3. Tonal range, (a) upper, (b) lower.
4. Timbre—discrimination.
5. Consonance and dissonance.

B. Intensity.

1. Sensibility.
2. Discrimination.

C. Time discrimination for short intervals.

II. Motor.

A. Pitch.

1. Striking a tone.
2. Varying a tone.
3. Singing intervals.
4. Sustaining a tone.
5. Registers.
6. Timbre: (a) purity; (b) richness; (c) mellowness; (d) clearness; (e) flexibility.
7. Plasticity: curves of learning.

B. Intensity.

1. Natural strength and volume of voice.
2. Voluntary control.

C. Time.

1. Motor ability.
2. Transition and attack.
3. Singing in time.
4. Singing in rhythm.

III. Associational.

A. Imagery.

1. Type.
2. Role of auditory and motor image.

B. Memory.

1. Memory span.
2. Retention.
3. Redintegration.

C. Ideation.

1. Association type and musical content.
2. Musical grasp.
3. Creative imagination.
4. Plasticity: curves of learning.

IV. Affective.

- A. Likes and dislikes: character of musical appeal.

²Localization of the tone is irrelevant and the spatial attribute of volume may for the present purpose be considered with intensity.

1. Pitch, timbre and harmony.
2. Intensity and volume.
3. Time and rhythm.
- B. Reaction to musical effect.
- C. Power of interpretation in singing.

The object of the sensory measurements is to determine to what extent the individual is psycho-physically capable of hearing music. For pitch appreciation, we may measure the discrimination, making sure that we reach the physiological as opposed to the cognitive limit of the perception of difference.³ A rapid survey at about twelve selected points within the range of pitch from 25 vd. to 2,500 vd. will suffice to ascertain if there are any gaps or any other peculiarities in the auditory sensibility to pitch within the range of tones which may be heard as musical. If any peculiarity is found, it may be surveyed in detail. To measure the tonal range of the ear, we determine the upper and the lower limit of sensibility to tone. The upper limit is, however, by far the most variable and important as a factor in musical hearing. The two ears may differ materially in range.

The perception of timbre may be measured by the ability to distinguish a pure tone from a series of artificially built-up clangs.⁴ The ability to analyze clangs

³ The cognitive limit is the limit set by lack of knowledge or training; the physiological is the limit beyond which one can not improve.

⁴ We suffer great confusion at the present time in regard to the use of the term, "quality" of tones. Psychologically, pitch is the quality of the tone, but in physics, oratory, music, and untechnical language, "quality" is used in the sense of timbre, tone-color, or character of the clang. Psychologically, the word, "timbre," alone should be used in this sense. It is timbre which distinguishes the tones of different instruments, the tenor from the bass when singing the same note, or the vowels of our speech. In each of these cases there is only a difference in the number of overtones and their relative dominance, for the tone is ordinarily a clang built up by the combination of a number of

varies with training, and should only be used as a measure of acquired efficiency or skill, although the capacity for such skill is determined mainly by the natural sensory capacity for perception of difference in timbre.

While the perception of consonance and dissonance depends largely upon training, there are fixed limitations in the natural sensory capacity which limit the possibility for appreciating the agreeableness or disagreeableness of combinations of tones. This ability may be measured by determining the ability of the singer in arranging a series of pairs of tones in the order of their consonance.

For the attribute of intensity, we should have at least two sensory measures: (1) the threshold of sensibility to tones in each ear; and (2) the discrimination for variations in the strength of a familiar, relatively pure, musical tone. These measures will show the natural capacity of the individual for the hearing of faint tones, the hearing of intensity accent, and the hearing of shadings in the strength and volume of tones in musical expression. The perception of volume is so intimately dependent upon the perception of strength of tone, that a separate measure is not needed.

While the perception of time is largely associational, we depend ultimately upon the sensory capacity for the perception of short durations and rhythmic effects. Rhythm may be expressed through both time and intensity. For a single measure of the perception of rhythm as a time element, we may eliminate intensity and measure the least perceptible deviation in the duration of the recurrent sound, uniform in all respects except duration. This, taken

partials or overtones, each having a pitch of its own. Timbre may therefore be regarded as a pitch complex.

together with the measure of intensity-discrimination, should correlate well with the measure of the perception of intensity in rhythm-accent.

In the survey of the motor capacity of the singer, we naturally follow the same divisions, according to the attributes of tones, as in the sensory; namely, pitch, intensity and duration of tones. There are four fundamental phases of simple pitch singing which should be examined separately: (1) simple ability to reproduce the pitch of a tone heard one second before the singing; (2) the ability to make faint shadings (sharp and flat) in pitch, (3) the ability to sing intervals, and (4) the ability to sustain a tone, both with reference to periodic and progressive changes in pitch. The record of the ability to sound the pitch of the tone should be taken at c' , 256 vd., and at points near the upper and the lower limits of the musical register of the voice. The voluntary control of the pitch of the voice, measured in terms of the minimal producible, sharp or flat, should all be recorded at the same three points in the register. The measure of ability in singing intervals should be taken (a) for two or three relatively pure intervals near the middle of the register of the voice, (b) for the singing of the natural scale, and (c) for the singing of the chromatic scale. The ability in the sustaining of the pitch of a tone for ten seconds may also be measured at the three representative levels of the register and should be so recorded as to show both progressive and periodic changes. Progressive changes are tendencies to gradually sharp or flat; periodic changes may be either regular or irregular oscillations in pitch, or a general lack of control.

The register of the voice should be stated in terms of the characteristic changes in timbre which take place near the upper

and the lower limits. Thus we may determine the range for agreeable musical tones, for tones easily sung, for chest tones and for true pitch singing. This series of records should be supplemented by a systematic description of the progressive change in the character of the tone from one end of the register to the other.

Under the head of timbre of the voice, the psychological-esthetic effect we seek to establish is the degree of beauty of the objective tone. We therefore eliminate subjective and circumstantial conditions and accessory features of the singing which may modify the agreeableness and disagreeableness of the given tone and consider only beauty as it is objective in the physical tone. This may be measured with considerable precision in terms of the form of the sound wave. From a single, well-chosen, graphic record of the voice, we may work out the following factors: (a) purity, the degree of approach to the smooth sine curve in the form of the wave; (b) richness, the number of overtones present; (c) mellowness, the character of the distribution of the overtones; (d) clearness, the uniformity in the form of a series of waves; (e) flexibility, the character of the progressive transition from one wave form to another. These purely objective measures of the beauty of the tone must be supplemented by systematic observations on the agreeableness of the timbre of the voice by experts judging separately each of the specific qualitative aspects of the voice as naturally used in singing. Objective record must also be made on the mode of tone production, especially characteristics of the resonance.

The plasticity of the individual in a given capacity is measured by the rate and character of the learning processes in that capacity. We now know enough about the characteristics of learning curves to be able

to determine in a relatively small number of trials the character of the prospect that an individual may have for acquiring skill in any given activity. The plasticity may be measured in this way for any of the motor processes of musical training. If but a single measure of plasticity is to be made, this may well be on the training in accuracy of transition from one note to another, involving the elements of release and attack.

As regards intensity of tone production, we are interested in the natural strength and volume of the tone and in the voluntary control of these factors. The strength of tone is expressed in terms of amplitude of vibration and should be measured in representative parts of the register. In so far as they differ from strength, carrying power and volume may be judged essentially in terms of the mode of tone production. Voluntary control of the strength of tone may also be measured in terms of the amplitude of the vibration. The measurement of voluntary control in the making of fine differences in volume, or in the change of volume as distinct from intensity of tone, is too complicated for our present purpose, but systematic observation of this in ordinary singing is essential.

Motor ability may be measured in terms of the degree of accuracy in the rapid enunciation of a selected list of syllables. The form of the attack is also an excellent measure of time-efficiency in musical action. But the most important of all time measurements is of course the ability to sing in accurate time and rhythm. For time alone, we test the singing of equal durations without accent. For rhythm, in the true sense, the singing must be with time and intensity variables together as in ordinary singing. The measure should be made for both simple and complex rhythm.*

* In measurements of motor ability, and rhythm in actual singing, the dictograph or some similar

A number of tests may be grouped under the general head of association, and these may be subdivided somewhat arbitrarily as in the outlined list. We should first secure a quantitative picture of the relative vividness of images from the different senses. Then the auditory image should be tested for fidelity, stability and relevance, in such a way as to reflect the rôle and power of auditory imagery in singing. The same may also be done for motor imagery.

The most fundamental fact about memory is the memory span for musical tones. This may be measured in terms of the number of tones (taken from a single octave, but not forming a known melody) the individual can remember for immediate reproduction or recognition. The power of retention may be measured by determining roughly the extent to which the singer can recall music heard a day or a week before. The power of musical redintegration may be tested by observing to what extent the individual can recall, in their true setting, the fine details of a complex musical production. Here the phonograph can be used to good advantage.

Association type may be given as the name for the sampling of the mental content and the prevailing mode of reaction as determined by free association experiments in what is now called psychoanalysis. This will show, for example, whether the individual lives in music objectively or if the music is to him merely a series of affective stimuli which arouse a feeling of idealized beauty. Most of the relevant facts which may be determined objectively by such diagnostic association tests may, however, be obtained by the expert through direct and unaided observation.

To the musical mind the sounds group themselves in large units, such as themes, movements, phrases, etc. The power of instrument may be used to excellent advantage.

grasp for musical complexes may be measured in terms of a graded series of complexes of musical units, taking in turn the various factors of pitch (including timbre and harmony), intensity and time.

A record of creative imagination may be obtained under experimental conditions by allowing the singer to improvise a tune for a selected stanza. The words of a series of stanzas should convey different types of emotional value. The ability may then be measured in terms of the merit of such a composition as preserved in the dictograph. Here the greatest freedom should be allowed the singer for spontaneous expression.

As knowledge of ability in learning music is essential, the mode of forming, and the natural ability for acquiring, new musical associations should be measured for one or more phases of vocal training, such as the placing of the voice, singing the chromatic intervals, or the analysis of clangs. If a single representative measure were to be made, this might profitably be the establishment of the learning curve for the singing of the untempered chromatic scale.

The affective phase of music is never isolated from the cognitive and motor elements, for both of these always involve some feeling. In such measurements as those of consonance, association type and creative imagination, we deal with facts which are quite as relevant to the affective as to the cognitive side of consciousness. The same principle applies also to some of the motor examples. The musical emotions are conditioned upon the various powers of appreciation and expression which we have just reviewed. Unless our singer has capacity for hearing or expressing a given musical effect, she can not experience emotional pleasure over it. The sensory, motor and associational measure-

ments have therefore determined the presence or absence of capacity for affective or emotional appreciation and expression. There are, however, three general surveys which are of a positive and fundamental nature; namely, musical preferences, reaction to musical effects and power of interpretation in singing.

One affective aspect of the character of the musical appreciation may be determined by working out the curve of likes and dislikes for representative series of musical selections. These should be so arranged as to represent the main types of musical appeal through each of the attributes of sound. Here the measurement may be standardized by having the graded selections furnished in a series of the best quality of phonograph discs. Three series might be used: (1) Pitch, timbre and harmony series; (2) the intensity and volume series; and (3) the time or rhythm series.

The amount and character of reaction to different musical effects may be observed under experimental conditions when the observer is not aware that this is being done; thus, a systematic record of such observations may be made under the guise of repeating the preceding measurement (IV., A, 1) in which the observer works by the method of impression just outlined. The curve for different kinds of mental and physical reactions observed may be made to parallel and supplement the curves for agreeableness and disagreeableness.

There are two aspects to the power of interpretation of music in singing; namely, the appreciation and the expression. Since expression involves appreciation, measurement on appreciation may be omitted. The power of expression may be measured by methods now in vogue for the measuring of merit. Musical experts may be obtained to make comparisons of one

specific element after another in singing under experimental conditions.

As a supplement to these measurements, there must be other measurements, statistical data, biographical information, and free observations regarding musical training, traits of temperament and attitude, spontaneous tendencies in the pursuit of music, general education and non-musical accomplishments, social circumstances and physique.

With this tentative plan of procedure before us as a concrete thing to consider, let us ask and answer the following three questions: How do these measurements acquire unity in meaning? Do they constitute an adequate measure of the singer? Of what practical significance can they be?

With reference to the first of these questions, it can readily be seen that a group of measurements like this is merely a group of samples of measurement. Their unity in meaning depends upon the degree to which they are adequately representative, and are interpreted in true perspective. They are meaningful only when compared with previously established norms, which show the mode and extent of distribution for a sufficiently large number of cases, and are interpreted in the light of the meaning ascribed to each level in the distribution. Take, for illustration, discriminative action in voluntary control of the pitch of the voice in singing. Reference to our norms shows, for example, that a record of .9 vd. means that this ability is within 3 per cent. of the best record for individuals under similar conditions, and that those who have such control are thoroughly qualified to render a high class of music in this respect; while a record of 9 vd. falls within 8 per cent. of the poorest ability measured, and is characteristic of an individual who can not sing; whereas 3 vd. represents the average ability of an untrained individual.

These norms must be worked out with much labor and skill in the interest of an avowedly applied psychology, and must be considered as problems in themselves before any measurements can be of service. During the last year or two a group of research men in the Iowa laboratory have been engaged in working out eight such norms in the psychology of music. After extensive preliminary development of methods and measuring instruments, they have aimed to secure records on two hundred individuals, constituting a homogeneous group for each norm. These norms are: pitch discrimination, vividness of tone imagery, span of tone memory, consonance and dissonance, rhythmic action, intensity discrimination, voluntary control of the pitch of the voice, and the singing of intervals. This is no simple undertaking, and so far the work can only be said to be preliminary. It requires the development of technique for each case, and the measurement must be taken for as many conditions as it is desired to vary under control.

This technique can not be mechanized so that every music teacher can handle it. Even after means and methods have been invented and standardized and norms have been established, it requires an expert, trained in the technique and skilled in the art. This is a field for the consulting psychologist in music, a person who devotes himself to this kind of work professionally. He must not only be able to determine the relative rank of a record by reference to the normal chart, but he must also be able to interpret the meaning of this rank in the light of the construction which has been placed upon the norm. He must be not only a technician, but an artist with appreciation for music, full of ingenuity, sympathetic and incisive in his interpretation. Like the so-called mind reader, he must have at his command a

large repertory of procedures, and be skilled in gathering information from all sorts of expected and unexpected sources during the experimental control. In this art he progressively simplifies procedure, divests himself of mechanical contrivances wherever possible, and takes the singer under more and more natural conditions.

The expert in mental measurement always remembers that the human individual is a psycho-physical organism. He must have records for the physical as well as the mental, and especially for their relationships; and he must interpret each fact, physical or mental, as a feature of an organism, bearing in mind that there is organization in the mental, just as truly as in the physical. With a clear grasp, on the one hand, of the fundamental attributes of objective music, and, on the other hand, of the fundamental capacities of the human organism for appreciating and rendering music, he must select that group of measurements which will answer his purpose: it may be a problem of learning; it may be an attempt to trace the nature of a discovered fault; it may be the proving-up of progress made under a given mode of training. Our present schedule of measurements is merely a sort of relief map for first orientation. The unity of the whole, or of any section, of such measurements lies in the effectiveness with which they serve one purpose.

In this work, systematic observation and description is supplemented by the concrete objective measurements. One of the main purposes of measurement is to secure experimental control of conditions in which systematic observation of factors under control may be recorded, though not a part of the numerical record.

Instead of neglecting what can be known by "common sense," as is often charged, the expert starts with this at its best, grad-

ually culls and sifts his facts in systematic observation, and finally clinches a few of the representative features in objective measurements. The charge that the so-called "practical man" knows more through direct impression, or common sense, than the expert can discover scientifically is a flagrant expression of ignorance. The effect of the scientific point of view is not to belittle the magnitude of music or man. But, as the astronomer sees more in the starry heavens than does the average man on a moonlight stroll, so the expert beholds in music and in the human individual vastly more than the so-called "ordinary man," in this case the mere musician, observes; for his vision is closer, more detailed, more keenly discriminating, recordable, repeatable and more penetrating.

In the Gibson girl we see a most realistic representation of form, face, hand, heart and mind. No stroke by itself has any meaning; no feature is really drawn; no mental faculty is actually represented in the cold, black lines. Yet, of a few rough strokes, the master mind has made such an *ensemble* that we have a true picture of beauty in the expression of physical and mental life. Just so our master of mental measurements will bring together facts, which in themselves may seem meaningless, into an *ensemble*, which adequately represents the individual singer, or some feature of her, for our purpose.

Turning to the second question, as to whether such a measure can be said in any sense to be adequate, let us take an illustration. A man has a richly varied and well-cultivated garden. He is an horticulturist and cultivates the garden for scientific observation, pleasure and table use. Now what would constitute an adequate measure of that garden? It is possible to determine to a high degree of accuracy the

exact size, form and weight of every living plant, the rate of growth of each and every leaf, root, flower and fruit, the absorption rate for each and every chemical element drawn from the soil, the rate of increase in tensile strength, the deposit of chlorophyll, the internal structure of each and every cell, etc., *ad infinitum*. The possibility of measurement is here practically unlimited. An adequate measure is, however, not a complete measure, but one which answers a purpose. The gardener measures the specific thing which he wants to know.

Now, the human psycho-physical organism is at least as rich and as varied as a well-cultivated garden, if we may make so crude a comparison. While mental measurements are not developed to the same degree of precision as those of the gardener, they are nevertheless possible and may be quite as serviceable. The question is not how many measures are possible. No sane individual would ever undertake to make all possible measurements on a singer. The question is this: Can we command measurements which shall answer our present purpose? In the present case, do these measurements give us an adequate estimate of the various capacities and qualifications of this individual as a singer? The list here given is therefore not an attempt to show how many can be made, but to suggest which of those available may answer our purpose, and, when taken together, prove an adequate measure.

In the way of mental measurements, we can get practically what we want, provided we are willing to deal with specific facts. Our present list makes a formidable array, yet it is limited to those for which I, though not an expert in this field, know methods and means of measurement, and to such as are essential to a reasonably representative survey of the matters to which

they pertain; and measurements which would result if any given point were followed up intensively are not mentioned. To the extent that they are representative and no essential feature is overlooked, they constitute an adequate measure of an individual as a singer.

There is a continual warfare between psychology, as a science, and the demands in practical life for a single general measure for some practical purpose. Much work has been done on the naïve assumption that a single measure of a cognitive capacity should serve as a general measure of intelligence. Space discrimination, reaction after choice, the memory span, and such specific cognitive measures have been used in seeking correlations with some sort of generally recognized intelligence, but of course in vain. For psychology demands that each measurement shall deal with something specific and fairly homogeneous, and the record pertains only to the factor under control. Our gardener's measure of the quality of tomatoes may or may not represent a quality of his potatoes, peas or roses. Each article must be measured by itself. So, only when we have collected a sufficient number of data to feel that all the essential and fundamental traits of intelligence are represented, can we speak of an adequate measure of intelligence. The same principle applies to the measure of musical ability.

Turning to the third question, as to the significance of a measure of a singer, we note that, if it is adequate, it places at the disposal of those who can profit by it a classified invoice of useful facts about this singer in such a way that it may be of direct value. The advice based upon such an invoice should be weighed by the expert, the facts should be laid before the teacher, and the pupil should realize that she has become objectified to herself in

such a way that she knows herself with reference to her possibilities as a singer better than she could possibly have learned in any other way. Her future career as a singer may be determined by this and like knowledge which may be gained from time to time. It is doing for her what an invoice does for the banker before he makes a large investment. If her case is promising the record is most stimulating and encouraging. If there is insuperable cause for failure, it may in a very true sense save life by preventing its wreckage upon the stage after long wasted effort. The record shows whether she is by nature endowed with the mind and body of a natural singer, and to what extent for each item; and it points out to her the high places and the low places in her capacities and possibilities. It substitutes procedure with knowledge, for the haphazard procedure which has always been followed in music.

In giving and taking advice of this sort we must, however, not forget the enormous resourcefulness of the human will, and the possession of latent powers. A one-legged man may become a rope dancer, a blind man a guide, a man with wretched voice an orator. Furthermore, art is possible only where there is willingness to overlook faults. A singer may be permanently lacking in some fundamental capacity and yet have such merits in other respects, or have such exceptional ability in covering, that she may be successful in spite of an overt handicap. But even then psychology has warned and explained.

This invoice also serves to explain experience of the past which may not have been understood. If the singer has had defeat, it will show exactly why. If she has been misguided in musical training, it may show the nature of the error and its results. If the singer is conscious of lack in some capacity, the record shows the na-

ture of this lack and may even suggest a remedy, if such there be. Even among the best musicians it is rare to find some one who does not have some type of difficulty. Indeed, the difficulties of the singer are notoriously great. If psychological measurement can lend a hand through the laying bare of the condition of the difficulty and by determining its nature and extent, as well as by discovering those who may not be aware of their genuine ability, it will indeed be in this respect a hand-maid of music.

Another effect of such measurements is not only to objectify the elements of musical appreciation and expression in such a way as to deepen insight in the expert, the teacher and the pupil; but it will also be reflected in the science and art of music as the scientific conceptions become generally known. The measurements will furnish a sort of skeleton for the psychology of music.

From the very nature of his art, the musician, as a rule, takes the same kind of attitude toward his performance as an author of high national reputation took to the Ouija board, which I had the pleasure of observing in action. In a certain sitting where the Ouija board was being shown, I remarked upon the extraordinary quickness of the sitter's eye in reading the spelled words. "Eye," he said. "Do you think I use my eyes?" "Let us try it. Close your eyes and proceed." Just as he started, I slid the board an inch to the side, and of course the rider did not hit a letter correctly. The performer was completely astonished. He had engaged in more than one hundred and fifty successful sittings, and yet he had not become aware of the fact that the use of his eyes was essential to his success. The message had come to him as a communication from without. The demand for so-called inspiration in

music develops this attitude. The musician proceeds with a remarkable unconsciousness of the elements involved both in the appreciating and performing of music. Any musician who is invited into the psychological laboratory where experiments in the psychology of music are performed, will demonstrate this, which is an entirely natural fact and casts no reflection upon him. The psychology of music for musicians has not yet come into existence. Its coming depends upon the recognition psychologists will give to the possibility of psychological measurements in music. The musician waits for the psychologist to blaze the trail. He is a most docile inquirer when opportunity is given. The perspective of music, and the perspective of the musician, which is gained by the objectifying of factors involved, will be projected into our common account of music, and this will vitalize musical ideas and furnish the singer a more general insight into his capacities and possibilities.

Such features of the psychology of music will form a foundation for musical pedagogy. Last year the director of a great symphony orchestra brought his instrumental and vocal soloists into the psychological laboratory and there performed a large number of experiments on them. Everything proved practically new to these musicians and yet they did not tire in pointing out what a great help each and every measurement would be in their training if they were available. Take one example—the measurement of the pitch of an instrumental or vocal tone as seen in direct reading on an instrument in the laboratory. Orchestra leaders and soloists continually differ in regard to the pitch sung or played under given circumstances. The director called up the players of the oboe, the French horn and the first violin, in turn, and the instant each played, the re-

cording instrument showed, to a small fraction of a vibration, how much the tone played varied from the true tone, and disputes of long standing were settled in a moment. The conductor then proceeded in the same way with his vocal soloists. They all saw their faults and fortes pictured quantitatively on the instrument, and left the laboratory unanimous in the verdict that the introduction of such psychological measurements into the conservatory would be a great step in the advancement of musical instruction.

It is the business of the psychological laboratory to develop measuring instruments and methods, and to standardize them because, when the musician employs any of these measurements, he is employing psychological, and not musical, technique.

Measurements of this sort may be divided into four groups according as they represent essentially natural capacity, plasticity (that is, capacity for learning), acquired skill, and knowledge; and, in each and all of these phases, the art of music would profit by such facts.

After all, pure psychology will be the chief gainer. One can not observe under controlled conditions in a field so rich and unworked without gathering new facts, correcting errors, broadening views and deepening insight into the nature of the mental processes involved in music. Applied psychology of music is to pure psychology of music as engineering is to physics; they must go hand in hand. Neither stands higher nor lower than the other in the rank of merit as a pursuit. And especially at the beginning of such an applied science as psychology, too high a value can not be placed upon the matter of laying solid theoretical foundations before we begin to work for practical results.

In conclusion, then, what is the lesson of

our illustration? The message I have attempted to convey may be stated in the following propositions:

1. Technical psychology may be so employed as to furnish qualitative and quantitative classified knowledge about a singer.

The question as to the nature of mental measurement does not enter into this discussion. That question has had its day. I am using the term measurement in the accepted sense in which we use it every day in the psychological laboratory, taking for granted that there is general agreement in regard to its nature and its limitations. The selection has been made on the theory that measurements of the kind we commonly accept in psychology may be so employed as to furnish a serviceable invoice of the natural capacity, plasticity, skill and knowledge a particular individual may have for doing a particular thing.

2. This more or less exact knowledge may be so gathered as to serve immediate and direct practical purposes. We have insistent demands for applied psychology from the various arts, professions and sciences. Our illustration shows how one such demand may possibly be met. The effect of such an illustration should be to awaken confidence in our method, to awaken a wholesome respect for actual facts, and to ward off superficial and hasty promises of results.

3. Applied psychology, if such there is to be, must be experimental in method and spirit. It is the introduction of the principle of measurement that has given us a science of pure psychology; and there will be no science of applied psychology until the same principle is believed in and acted upon seriously by those who would make its applications. This does not imply a narrow insistence upon experiments everywhere, but rather a whole-hearted accept-

ance of the spirit of experimental method.

4. There is need of consulting psychologists, trained in pure psychology and in the work to which it is to be applied, who shall devote themselves professionally to applied psychology. The field of the psychology of music is promising.

5. This attitude of modern psychology toward the human individual and the art of music will lead to a keener and more penetrating insight into the nature and the conditions of both the individual and his art, and this will result in helpful guidance and a more vital appreciation and respect for the wondrous possibilities of the singer and the song.

6. We must not entertain the idea that applied psychology is to live merely upon the crumbs that fall from the table of pure psychology, nor that it can be reduced to a set of ready-made rules which may be handed down to the uninitiated. Applied psychology "must recognize itself, its diversities, its stupendous difficulties, its essential limitations and withal its promise and worth."⁶

CARL E. SEASHORE

UNIVERSITY OF IOWA

THE AMERICAN SCHOOL HYGIENE ASSOCIATION

THE next meeting of the American School Hygiene Association is scheduled to occur in Boston, March 28, 29 and 30, probably at the Harvard Medical School. The following is a partial program for the meeting: Demonstrations of ventilating systems, school nursing, medical inspection, out-of-door schools and school furnishings in certain public and private schools of Boston; reports of committees on "Ventilation," and on "Standardization of School Books"; papers by Dr. Ernest B. Hoag, lecturer on hygiene, University of California; Willard S. Small, principal, Eastern High School, Washington, D. C.;

⁶ Seashore, "The Consulting Psychologist," *The Popular Science Monthly*, March, 1911, p. 290.

Henry H. Goddard, director of research in the Training School for Backward and Feeble-Minded Children, Vineland, N. J.; Guy Montrose Whipple, Cornell School of Education; Dr. G. S. C. Badger, Boston, Mass.; David Snedden, Massachusetts Commissioner of Education; Dr. Thomas D. Wood, Teachers College, New York City; L. N. Hines, superintendent of schools, Crawfordsville, Ind.; William H. Burnham, professor of pedagogy and school hygiene, Clark University; Dr. Leonard P. Ayres, Russell Sage Foundation; David Spence Hill, Tulane University; Miss Alice L. Griffith, San Francisco; "Hygiene of Swimming Pools in Schools and Universities," Dr. M. P. Ravenel, director, Wisconsin State Hygiene Laboratory; "The Deaf Child," Dr. Helen MacMurchy, Toronto; "Contagious Skin Diseases in Relation to Schools," Dr. C. J. White, Boston; "Defects in the School Curriculum in Physical Training shown by the Disabilities of College Students," Dr. Dudley A. Sargent, Harvard University; "Health Problems encountered in Home Visits to School Children," Dr. A. E. Shipley, Brooklyn, N. Y.; "The Mentally Defective Child," Dr. Isabel Thompson Smart, New York City; "Recent Tests of Heating and Ventilating Apparatus in Public Schools," Frank I. Cooper, Boston; "The Hygiene of the Ear," Dr. C. J. Blake, Harvard Medical School; "Ventilation," Dr. Luther H. Gulick, director, department of child hygiene, Russell Sage Foundation; "The Hygiene of the Nose and Throat," Dr. E. A. Crockett, Boston; "The Importance of School Hygiene from the School Committee Standpoint," Joseph Lee, president, Playground Association of America; "Applications of Hygiene in a Preparatory School for Boys," Dr. Elias G. Brown, director, the Mountain School for Boys, Allaben, N. Y.; "Scoliosis in Relation to School Life," Dr. Robert W. Lovett, Harvard Medical School; "Venereal Contagious Diseases in Children as affecting School Conditions," Dr. W. P. Lucas, Harvard Medical School; "Sewage Disposal in Rural Schools," Dr. J. N. Hurty, state commissioner of

health, Indiana; "School Room Air and Its Relation to Disease," Dr. M. J. Rosenau, Harvard Medical School, and "Oral Hygiene," by Dr. W. H. Potter, Harvard Dental School.

THE ROCKEFELLER FOUNDATION

MR. JOHN D. ROCKEFELLER has consented to a modification of his plan for the establishment of the Rockefeller Foundation under federal auspices in deference to criticism in congress and from other sources.

The modified bill has been introduced in the senate and house. The changes in the scheme are: (1) Congress to retain the right to impose such limitations on the objects of the corporation as public interest may demand. (2) The total amount of property to be held by the Foundation is limited to \$100,000,000. (3) The income of the corporation is not to be added to the principal. (4) The foundation may wind up its affairs in fifty years, or congress may do so after a century has passed. (5) Instead of being a self-perpetuating corporation, its new members are to be chosen subject to the veto of an outside body.

SCIENTIFIC NOTES AND NEWS

DR. GEORGE JARVIS BRUSH, emeritus professor of geology in the Sheffield Scientific School of Yale University, eminent for his contributions to the science of mineralogy, died on February 6, aged eighty years.

It is proposed to have painted and to present to the American Philosophical Society a portrait of its president, Dr. William W. Keen, who, on January 19, celebrated his seventy-fifth birthday.

DR. CHARLES E. MUNROE, professor of chemistry and dean of the Faculty of Graduate Studies at George Washington University, who has completed his fortieth anniversary as an academic investigator, educator and administrator, will be given a banquet at the Cosmos Club, Washington, on the evening of February 23.

THE American Museum of Safety has presented its gold medal to Dr. Alvah H. Doty for progress and achievement in the promotion of hygiene and sanitation and the mitigation of occupational diseases.

M. LOUIS GENTIL has been elected president of the French Geological Society.

THE Geological Society of London will this year award its medals and funds as follows: Wollaston medal, to Mr. Lazarus Fletcher, F.R.S.; Murchison medal, to Professor Louis Dollo; Lyell medal, to Mr. Philip Lake; Wollaston fund, to Mr. C. I. Gardiner; Murchison fund, to Dr. Arthur Morley Davies; Lyell fund, to Dr. A. R. Derryhouse and Mr. R. H. Rastall.

At a recent meeting of the Rumford Committee of the American Academy of Arts and Sciences, a grant of \$250 in addition to former appropriations was made to Professor A. L. Clark, of the Kingston School of Mining, in aid of his research on the physical properties of vapors in the neighborhood of the critical point.

DR. FREDERICK CHEEVER SHATTUCK has resigned the Jackson professorship of clinical medicine at Harvard Medical School, which he has held for the past twenty-four years. Dr. Shattuck will become professor emeritus on September 1, 1912.

DR. C. RAUNKIÄR has been appointed professor of botany and director of the botanical garden at Copenhagen in succession to Professor Eugene Warming, who retires from active service.

SIDNEY L. GALPIN, instructor in mineralogy, Cornell University, has been appointed assistant state geologist of Georgia, to succeed Otto Veatch, who accepts a position with the U. S. Bureau of Soils.

MR. A. C. VEATCH, having returned from a year's examinations and explorations in the Trinidad and Venezuela oil fields, and having resigned from the U. S. Geological Survey, where he was geologist and chairman of the land classification board, will practise as a consulting geologist.

DR. MAX UHLE has resigned the directorship of the Museo de Historia Nacional at Lima, Peru, and accepted the offer of the Chilean government to take charge of its archeological research, with headquarters at Santiago.

DR. GEORGE BRUCE HALSTED'S "Rational Geometry," has been translated into the French language by M. Paul Barbarian and published by Gauthier-Villars. The book has also been translated into German and Japanese.

PROFESSOR WM. PATTEN, of Dartmouth College, and Mrs. Patten sailed from San Francisco on January 24 for Honolulu, Fiji, Auckland and Sydney. His book on "The Origin of Vertebrates," of which he has just finished the proofreading, will soon be published by P. Blakiston's Sons, Philadelphia.

PROFESSOR ALEXANDER SMITH, head of the chemistry department of Columbia University, lectured before a joint meeting of the Syracuse Chapter of Sigma Xi and the Syracuse Section of the American Chemical Society on the evening of January 19, on "Some Essentials in the Teaching of Chemistry which are often neglected."

DR. WALDEMAR KOCH, assistant professor of pharmacology in the University of Chicago, known for his important researches in the chemistry of lecithin and of the brain, and on the quantitative study of animal tissue, died of pneumonia on February 2, aged thirty-six years. Dr. Koch was the nephew of Robert Koch.

MR. CHARLES FINNEY COX, treasurer of the New York Academy of Sciences and of the New York Botanical Garden, past-president of the academy and the author of contributions on botanical and zoological histology and the theory of evolution, has died at the age of sixty-six years.

CHARLES GILBERT WHEELER, assistant state geologist of Missouri from 1859 to 1861, professor of chemistry in the old University of Chicago, from 1868 to 1889, since then consulting mining geologist and mining expert, died on January 30 in Chicago, at the age of seventy-five years.

DR. SOPHIA JEX-BLAKE, who was responsible for the foundation of schools of medicine for women in London and Edinburgh, and practised medicine for many years in Edinburgh, has died at the age of seventy-two years.

UNIVERSITY AND EDUCATIONAL NEWS

CONDITIONAL gifts of \$100,000 to Washington and Jefferson College at Washington, Pa., toward a \$500,000 fund, and \$50,000 to the Emory and Henry College at Emory, Va., toward a \$250,000 fund, were voted at a meeting of the General Education Board of the Rockefeller Foundation on January 26. Frederick T. Gates was reelected chairman and Wallace Buttrick, secretary of the board for 1912. These two officers and Robert C. Ogden, Walter H. Page, John D. Rockefeller, Jr., Starr J. Murphy and Edgar L. Marston form the executive committee. Jerome D. Greene, business manager of the Rockefeller Institute for Medical Research, was elected a member of the board.

CORNELL UNIVERSITY again has a forestry faculty. One year ago Mr. Walter Mulford, junior professor of forestry in the University of Michigan, was appointed professor of forestry at Cornell, and has been in Ithaca since last summer. This fall Mr. John Bentley, Jr., formerly of the U. S. Forest Service, was appointed assistant professor in the department. And now Professor Filibert Roth, who for the past nine years has been at the head of the forest school at the University of Michigan, has accepted appointment at Cornell as professor of forestry and head of the department. The forestry work is a department of the New York State College of Agriculture at Cornell University. The department plans to give a thorough professional course.

DR. HUGH P. BAKER, professor of forestry at Pennsylvania State College, has been appointed to fill the newly created post of professor of forestry at the University of Illinois.

MR. A. W. NOLAN, of West Virginia University, has been appointed assistant professor of agriculture. Dr. B. E. Powell, formerly private secretary to President James, has been appointed journalist in the College of Agriculture and Experiment Station.

DR. J. B. WOODWORTH has been promoted to an associate professorship of geology at Harvard University.

PROFESSOR W. A. BONE, F.R.S., Leeds University, has been appointed professor of fuel and refractory materials in a new department of applied chemistry now being established in the Imperial College at South Kensington, London.

PROFESSOR HESS, of Würzburg, has received a call as director of the eye clinic of the University of Berlin.

DISCUSSION AND CORRESPONDENCE

FORMATION OF CLOUDS OVER FIRES

TO THE EDITOR OF SCIENCE: In your issues of May 15, 1908, and October 23, 1908, there appeared letters describing the formation of clouds observed above the column of smoke from large fires. In the latter letter, by Wm. F. Wallis, no mention of the character of the clouds thus formed is given; I am under the impression that Mr. B. M. Varney, in his letter of May 15, described these clouds as cumulus clouds, but as I have not that number of SCIENCE before me can not now be sure that he did so describe them. If previously noted occurrences of clouds over fires have been of cumulus clouds, it may be of interest to note a formation of a slightly different type.

On the morning of November 16, 1911, the revolutionary forces attacked the city of Foochow, and set fire to the Manchu quarter of the city. The fire burned more or less fiercely for some twenty-four hours. About 1:05 P.M. on the 9th, when the air temperature was 70°, the relative humidity 52 per cent., and the sky otherwise cloudless, there appeared at the top of the smoke column rising from the city a white cloud closely resembling the fracto-cumulus. The cloud maintained its position over the column of smoke for only a very few minutes, and then melted away, but was followed some fifteen minutes later by a similar cloud, which soon disappeared. How frequently and at what intervals this formation and disappearance occurred I do not know, but several times later until about 4:30 P.M. similar clouds were observed for a few minutes. These clouds were at about the average height of cumulus clouds, and would seem to have been formed, as Mr. Varney suggests, by

the draft carrying water vapor (in not very large quantities in this case) upwards to a level of cloud formation.

WALTER N. LACY

FOOCHOW, CHINA,
November 11, 1911

ENDOCRYPTA HUNTSMANI

TO THE EDITOR OF SCIENCE: My attention has been called to the fact that the generic name "*Crypta*," used on page 19, in my paper on "The Hydroids of the West Coast of North America," published May 13, 1911, as a bulletin from the Laboratories of Natural History of the State University of Iowa, had previously been applied to another genus. I shall change it, therefore, to "*Endocrypta*," a name that I believe has not been used, and one that is equally significant. The new species described should, therefore, appear as *Endocrypta huntsmani*.

C. McLEAN FRASER

SCIENTIFIC BOOKS

The House Fly—Disease-carrier. An account of its dangerous activities and of the means of destroying it. By L. O. HOWARD, Ph.D. New York, Frederick A. Stokes Company, Publishers. Pp. xx and 1-312; 40 figs. and 1 colored plate.

I am glad Dr. Howard starts his little book with a colored plate illustrating his subject, because it is a good one and because it explains, if we study it carefully, why, when we look at the fly with a good even if low-powered lens, it looks like a pretty combination of soft velvety browns and tans, while if you look at it with the unaided eye you see only a uniform pale gray. There are other, most excellent figures of the house fly, his various parts and stages in the book, a few of them original, most of them from good modern sources, and altogether the book is well and practically illustrated throughout, to the very last sanitary privy.

There is no doubt but that Dr. Howard knows his subject and no doubt either that he who reads it will learn much concerning the fly problem: he will marvel, however, at how

much we already know, at how much work has been done throughout the world and at how much is yet unknown and remains to be done.

Dr. Howard gives us the systematic position, the structure and the general development of the house fly, or, as he frequently drops into saying, the typhoid fly, and on these points he speaks with authority and from personal knowledge. In working over in detail the habits of the various stages he brings together the literature of the subject from practically all over the world and makes a very readable account of it indeed. It shows that the house fly has long attracted attention, everywhere.

In dealing with the adult stage, the function of the insect as a disease-carrier comes in for careful consideration and this part of the book is at once the most interesting and valuable. Dr. Howard is fully convinced of the culpability of his culprit, and he marshals the evidence against him in absolutely convincing form. I doubt whether it is possible to read this series of chapters or sections showing the connection between the various germ diseases and their transmission by fly agency without feeling that a genuine conservatism had animated the writer in his investigation. Antagonistic evidence is brought out and explained and a full bibliography of the subject is given.

It is surprising to find that the house fly has no considerable number of natural enemies capable of keeping it in check and that one of our most promising methods of control rests upon a partially unverified statement concerning the insect's life history.

By the lay reader those sections dealing with the practical handling of the pest will have the most careful scrutiny and these sections have been most carefully written. Dr. Howard has not only had personal experience with practical work in Washington; but has probably seen and conferred with every man who has had a real campaign to carry out. He is therefore very conservative in his suggestions and points out difficulties as well as successes. He also points out that actual number of flies alone, no matter how disgusting, is not always indicative of the presence of

disease and he furnishes abundant suggestions upon which intelligent fly campaigns may be based when the local conditions rendering them necessary are fully understood.

JOHN B. SMITH

NEW BRUNSWICK, N. J.,
January 17, 1912

Die Palaeobotanische Literatur. By W. J. JONGMANS. Zweiter Band—Die Erscheinungen des Jahres 1909 und Nachträge für 1908.

In the issue of SCIENCE for August 26, 1910, the writer published an account of the initial volume of Jongman's "Paleobotanical Bibliography," which covered the year 1908. The second volume of this laborious undertaking has just been distributed. It is from the press of Gustav Fischer, of Jena, and aims to include all of the contributions to paleobotanical literature that were published during 1909. Additions for 1908 that were omitted in the first volume are included and all of the species described or mentioned in the discussions, together with the geological horizons, are arranged alphabetically, and this, the main part of the work, is preceded by a list of the contributions numbered chronologically and arranged by authors.

The present volume makes a book of 417 pages, or about twice the size of volume one, and fully maintains the high standard of the latter. It is indispensable to the working paleobotanist. Botanists, geologists and bibliographers also owe Dr. Jongmans a debt of gratitude.

Individuals and institutions can cooperate in the continuation of this valuable work by sending their publications promptly to the author in care of the Royal Herbarium at Leiden, Holland.

EDWARD W. BERRY

SCIENTIFIC JOURNALS AND ARTICLES

In the *Philippine Journal of Science*, Section D, No. 4, Dean C. Worcester describes newly discovered breeding places of Philippine sea birds, illustrated with half-tone plates which show great numbers of boobies and

terns which are apparently without any fear of the photographer. The same author also notes a probable hybridism among boobies. R. C. McGregor reports the capture of *Puffinus chlororhynchus* Gould off the coast of Luzon, and describes a new species of noddy tern, *Micranous worcesteri*, from Cavilli Island in the Sulu Sea. R. W. Shufeldt's article on the skeleton in the flying lemurs is concluded. A. S. Pearse presents notes on the habits of *Thalassina anomala* (Herbst), and concerning the development of frog tadpoles in sea water. Section B, No. 4, contains two papers on amœbæ found in the Philippine Islands. In one Ernest Linwood Walker makes a comparative study of the amœbæ in the Manila water supply, in the intestinal tract of healthy persons, and in amœbic dysentery and shows that all hitherto cultivated amœbæ are non-pathogenic, but that the true pathogenic amœba can not be cultivated; in the other Andrew Watson Sellards discusses immunity reactions with amœbæ. Weston P. Chamberlain presents a statistical study of typhoid fever in the Philippine Islands; a map shows the distribution of typhoid fever in the Islands. Horace D. Bloomergh presents data relative to the Wassermann reaction in syphilis, leprosy and yaws. In Section A, No. 4, Alvin J. Cox discusses Philippine soils and some of the factors which influence them, the chief among these being the division of the Philippine Islands into regions because of types of rainfall. Raf. A. Herrmann presents a theory on the formation of the central Luzon plain. Benjamin T. Brooks describes essential oil from *Michelia champaca* L. and discusses its chemical constitution. He also gives a study of a number of other new Philippine essential oils and reviews the fluctuations in the value of ylang-ylang.

NOTES ON ENTOMOLOGY

MR. E. E. AUSTEN has produced another book on the tsetse-flies.¹ A few years ago

"A Handbook of the Tsetse Flies (Genus *Glossina*)," British Museum, 1911, 110 pp., 10 pls., 24 text figs., 1 map.

these flies were practically unknown to entomologists, and even specimens were rare in museums. Since their connection with disease has been proved, Mr. Austen has had the opportunity of examining thousands of specimens. The author adopts the division of the genus into three sections as proposed by Mr. Newstead, but does not rely as much as that author upon the structure of the genitalia for separating species. Fourteen species are recognized, and one considered uncertain. The puparia of six species are figured, and are all extremely similar in appearance. The illustrations (by Terzi) are all that one could desire.

AN interesting review of the fleas infesting the domestic animals is furnished by Dr. K. Wolffhügel.³ Following a general account of the structure, habits and life-history of fleas, is a descriptive list of twelve species. The generic name *Dermatophilus* is used in place of *Sarcopsylla*, although the latter has four years priority. A host-list, and a bibliography is appended.

MR. H. ELTRINGHAM has issued a large book summarizing his studies on the mimetic butterflies of Africa.⁴ Each species is treated under the mimetic association of which it is considered a member. These associations are based upon certain general plans of coloration. He shows that many of these butterflies are distasteful to birds, and that the butterflies eaten or attacked by birds are mostly non-mimetic species.

MR. R. SHELFORD, who has published recently on the cockroaches of amber⁵ finds that all the genera are recent ones, and that one species, *Euthyrrhapha pacifica*, is the same as a species now widely distributed in the tropics, but never recorded from Europe. This is not a primitive cockroach, but a highly

³ "Die Flöhe (Siphonaptera) der Haustiere," *Zeit. f. Infektionskr., par. Krankh. Hyg. Haustiere* VIII, pp. 218-236, 354-382, 25 figs., 1910.

⁴ "African Mimetic Butterflies," Oxford, 1910, 136 pp., 10 pls. col.

⁵ "The British Museum Collection of Blattidæ Enclosed in Amber," *Journ. Linn. Soc. Lond. Zool.*, XXXII, pp. 59-69, 1 plate, 1911.

specialized one. The specimen is marked much like the common form in South Africa. About ten species are described as new, some prettily maculated with yellow and brown.

MR. B. H. WALDEN is the author of the "Orthoptera of Connecticut" in the series which Professor Britton proposes to publish on the insect fauna of that state.⁶ There are descriptions and synoptic tables to genera and species, and many notes on the habits of the 100 species now known from that state. It will be a most useful work for the beginner, and if the other parts can be carried out in the same excellent manner the "Guide" will be one of the most valuable works on North American entomology.

RECENT parts of the "Catalogus Coleopterorum" are No. 29, Staphylinidæ, Part II., pp. 87-190, by M. Bernhauer and K. Schubert; No. 30, Cioidæ, 32 pp., by K. W. von Dalla Torre; one of our species *Cis bimaculatus* Kraus is changed to *C. krausi* because of preoccupation, and No. 31, also by Dalla Torre on the Aglycyderidæ, one species from the Canary Islands, and the Proterrhinidæ, only represented in the Hawaiian Islands; No. 32 on the Hydroscephidæ, by E. Csiki, 61 pp.; No. 33 by Dalla Torre on Nosendridæ, Byrrhidæ and Dermestidæ, 96 pp.; No. 34 on Erotylidæ, by P. Kuhnt, 106 pp.; No. 35 by J. Weise, on the Hispinæ, 94 pp., and No. 36 on the Anthicidæ, by M. Pic, 102 pp., these with many species in our country.

THE problem of the classification of the Coleoptera has been attacked from a new point by Dr. P. Netolitzky,⁷ who has investigated the structure of the paramera in a number of genera. These paramera, which are basal pieces of the male genital organs, are usually asymmetric in most of the Carabidæ, in *Patrobus* and allies but slightly so, in

⁶ "The Euplexoptera and Orthoptera of Connecticut; Guide, Insects Conn.," Part II., Bull. 16 State Geol. Nat. Hist. Survey, pp. 39-169, 5 plates, 1911.

⁷ "Die Parameren und des System der Adephega (Caraboides)," *Verh. zool.-bot. Ges. Wien*, 1911, pp. 221-239.

Pterostichus and *Pseudomorpha* very strongly asymmetric. In *Carabus*, *Calosoma* and *Cychnus* they are symmetric, and also in some families allied to the *Carabidæ*. He considers these parts will furnish useful clues to the relationship of families and smaller groups.

DR. C. WESENBURG LUND, who has been studying the habits of caddice flies has recently published two articles on the larvæ. In one¹ he describes and figures the nets of most of the Hydropsychidæ found in Denmark, and also describes the structure of the larvæ. He considers the Rhyacophilidæ an ancient family, and the Hydropsychidæ a more recent and highly specialized one.

In the second article² he gives an account of the life-history and larval habits of a large and common caddice-fly. The carnivorous larva builds a spiral case of parts of leaves or sticks, which is gradually enlarged and lengthened as the creature increases in size.

Useful bibliographies accompany each paper.

DR. N. ANNANDALE has described³ a new genus (*Ramcia*) which is intermediate between the true mosquitoes and the series of genera known as *Corethinæ*. The proboscis is short and weak, but the veins of wings bear prominent scales, and the entire wing-margin is provided with a fringe of long scales. There are no scales on the thorax. The larva and pupa are also described, being related to *Corethra*. The single species comes from Ceylon.

AMONG recent fascicles of the "Genera Insectorum" of M. Wytzman, a number are of interest to us. Fascicle 110, by H. Schmidt, "Biologische Studien über netzspinnende Trichopterenlarven," *Intern. Rev. Hydrobiol. Hydrog.* (Biol. Suppl., III. Ser.), V., pp. 1-64, 1911, 5 pls.

"Ueber die Biologie der *Phryganea grandis* und über die Mechanik ihres Gehäusebaues," *Intern. Rev. Hydrobiol. Hydrog.*, IV., pp. 65-91, 2 pls., 1910.

"A New Genus of Short-beaked Gnats from Ceylon," *Spolia Zeylanica*, VII., pp. 187-193, 1 plate, 1911.

is on the Aphodiidæ (part of the old *Scarabæidæ*), 155 pp., 3 pls.; fasc. 111, by Max Hagedorn, on the Ipidæ (Scolytidæ), 178 pp., 14 pls.; three of the plates show galleries and four show structural details; fasc. 113 on the Orthalid flies of the sub-family Richardinæ, 56 pp., 3 pls.; fasc. 114, by G. V. Szepliget, on part of the ichneumon flies of the Ophioidæ, 100 pp., 2 pls.; fasc. 115, by R. Martin, on the *Æschinæ*, 34 pp., 5 pls.; fasc. 116, 117, by P. Dupius, on two small groups of Carabidæ; fasc. 118, by C. Emery, on the ants (Formicidæ) of family Ponerinæ, 125 pp., 3 pls.; fasc. 119, by J. A. G. Rehn, on the Mantid sub-family Vatinæ, 28 pp., 1 pl.; fasc. 120, by A. N. Caudell, on a small group of Locustidæ; fasc. 121, by W. D. Pierce, on the Strepsiptera, 54 pp., 5 pls.

NATHAN BANKS

SPECIAL ARTICLES

NOTICE OF A NEW GENUS OF RHINOCEROS FROM THE LOWER MIOCENE

DURING the past few years, several of the many collectors from various institutions, who have collected in western Nebraska and eastern Wyoming, have found fragments of a very large rhinoceros in the Harrison beds, which occur in that region. Mr. E. S. Riggs, of the Field Museum of Natural History, of Chicago, found certain upper molars which he took to be those of some primitive species of *Teleoceras*. But all of these "finds" have been quite fragmentary, and no particular attempt has been made to accurately classify them.

The writer had the good fortune last summer to find additional material of this type, and upon careful examination is convinced that a new genus—or at least a new sub-genus—is here represented.

Epiaphelops virgascetus, gen. et sp. nov.

Dental formula, $M_3^?$, $P_4^?$, $C_0^?$, $I_1^?$. Type No.

H C 265, collection of the writer. The specimen taken as the type is a right lower jaw, with complete dentition, and the anterior part of the left lower jaw.

Epiaphelops is separated from *Aphelops*, to

which genus it appears most nearly related, by (1) the presence of a functional P_1 of good size. This tooth is absent in *Aphelops*; (2) by a much more brachyodont dentition; (3) by the presence of a heavy external and internal cingulum on all teeth of the grinding series, but the last molar, where it is reduced.

This brachyodont condition, as compared with *Aphelops*, corresponds to the difference in horizon, assuming them to be in the same approximate ancestral line. The typical *Aphelops megalodon* is from the Middle Miocene, the present genus and species from the Lower Miocene.

Epiaphelops does not appear to be derivable from *Canopus*, as in all known species of *Canopus* the first lower premolar is absent, or a vestigial, variable, character. In this respect *Epiaphelops* is more primitive than *Canopus*, as P_1 is large and functional. Comparison with other Oligocene types does not appear profitable.

Epiaphelops virgascetus is somewhat larger than *Aphelops megalodon*. As the other specimens in the collection of the writer referable to this type are not surely associated, they are best unpublished for the present, but suffice it to say that when this form is better known, other characters are present which will more clearly characterize it. A more complete description will appear later.

HAROLD JAMES COOK

AGATE, NEBRASKA,
December 20, 1911

THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE
SECTION A—MATHEMATICS AND
ASTRONOMY

As the Astronomical and Astrophysical Society of America held a regular meeting in affiliation with the American Association, and as the American Mathematical Society held its annual meeting at the same time in New York City, the special program of Section A was confined to one session. This was a joint session with the Astronomical and Astrophysical Society, and the program consisted of the vice-presidential address by E. H.

Moore, of the University of Chicago, and of two papers given, on special invitation, by J. A. Metcalf and Lewis Boss.

An abstract of the paper by Lewis Boss, entitled "Recent Researches as to the Systematic Motions of the Stars," is as follows:

The proper motions of stars are so small, and are so difficult to measure with proportionate accuracy that the successful determination of systematic peculiarities in the arrangements of the motions themselves must depend upon great systematic accuracy in the measurements of those motions. Therefore, when the department of meridian astrometry was established at the Dudley Observatory about six years ago with the support of the Carnegie Institution of Washington its first work of investigation was to continue to completion the work it had begun with the object of ascertaining the proper motions of the brighter stars which had been most observed with precision in the past, with all practicable completeness and accuracy, both in the casual and systematic sense, with the ultimate purpose of making this work the basis of studying the systematic peculiarities of these motions in order to throw further light on the mechanism of the visible universe.

About two years ago the Carnegie Institution of Washington published the result of this research in a volume entitled "Preliminary Catalogue of 6,188 Stars." For each star the position was given for 1900 together with the proper motion, etc., necessary for reducing those positions to any other epoch. This material was first employed for deriving new values of the precession as well as the direction of solar motion. The latter was found to be, for 1875: R.A. $270^\circ.7$, Decl. $+34^\circ.3$ (A.J. 614). The stars employed in this discussion cover the entire sky from the north to the south pole; so that the direction of the solar motion came out with very great weight and at the same time independently of the precession.

Next were deduced the facts in regard to an interesting moving cluster of stars in the constellation, *Taurus*. Each of the 41 stars appears to be moving toward a point in the sky in R.A. $6^\circ 7^m$, Decl. $+7^\circ$. The velocities of motion of the several stars are approximately the same. Very recently Mr. Benjamin Boss, of the department of meridian astrometry, identified a group of 11 or 12 large proper motions scattered widely over the sky between declinations $+42^\circ$ and -81° , which converge nearly in a point at R.A. $6^\circ 37^m$, Decl. $+0^\circ.5$. The velocities of these stars toward the point cited seem to be uniformly about 95

kilometers per second. 61 *Cygni* appears to be a member of this group (A.J. 629).

Before seeking a systematic representation in direction and amount of the star motions generally the speaker had wished first to follow up the indications which had already appeared to the effect that the stars of differing spectral types are moving with differing mean velocities. Frost, eight years ago, had offered the earliest evidence that the Helium, or *Orion*, stars are moving slowly in comparison with those of older types. Quite recently he and Kapteyn and also Campbell added some preliminary evidence to the discussion of this question. In the winter of 1910-11 the department determined to take up this subject comprehensively by employing the cross-motion element of the proper motions. The results of this research on acceleration of stellar motion were published in the *Astronomical Journal*, Nos. 623 and 624. These results are given in the following table under the column designated "mean cross motions." For comparison, Campbell's results from mean radial motions are given in the next column. They were obtained from entirely different sources, independently and almost simultaneously. The letters in the first column, in which *B* is supposed to stand for the youngest spectral type (Helium), and *M* for the oldest considered in this investigation, are designations adopted from the Harvard classification (H. C. O., Vol. L.).

Type	Mean	Mean
	Cross Motions	Radial Motions
<i>B</i>	6.3	6.2
<i>A</i>	10.2	10.5
<i>F</i>	16.2	14.4
<i>G</i>	18.6	15.9
<i>K</i>	15.1	16.8
<i>M</i>	17.1	17.1

The cross motions were originally expressed as a fractional part of the centennial motion of the sun. Both series, in good agreement, express the fact that the motion of a star accelerates up to about the time the spectrum develops into type *F* or *G*, after which it seems to gain no increase of velocity.

Seven years ago Professor Kapteyn, at the Scientific Congress of the St. Louis Exposition, introduced his now well-known hypothesis that the visible universe consists of two great intermingling streams moving in opposite directions. The direction of one he called the "vertex," which he fixed at R.A. $6^h 4^m$, Decl. $+13^\circ$. Quite recently Edding-

ton, of the Greenwich Observatory, with the same hypothesis, and using the proper motions of the "Preliminary General Catalogue," found for this vertex: R.A. $6^h 16^m$, Decl. $+12^\circ$.

In 1907 Schwarzschild advanced the hypothesis that a systematic arrangement of the proper motions leads to an ellipsoidal arrangement of distribution and he endeavored to show that the proper motions of Groombridge's Catalogue are as well represented as they are by the hypothesis of two streams.

By a method entirely different from that employed by either of the two investigators, the department found nearly a year ago that when its proper motions were compared in a manner to bring out this systematic arrangement, it was seen that if all the actual motions of the stars in any considerable area of sky were brought to a common origin (freed from their solar parallactic motions) the figures so constructed would have an elliptic outline, which turned out to be different presentations of an ellipsoidal figure of which, if the major axis be taken as 7, the two minor axes would be 4. The major axis of all the figures points very nearly toward the vertex of Kapteyn; this point was found to be in R.A. $6^h 15^m$ and Decl. $+7^\circ$. Moreover, these ellipsoids have well-marked nuclei composed chiefly of stars of types *B* and *A*. This fact would require a third stream to complete the "two-stream" hypothesis, as some of the supporters of the latter have already perceived.

The speaker presented considerations in support of his belief that this ellipsoidal arrangement of the star-motions in space would be reduced to a simple and natural explanation, if we suppose that the stars had been originally formed in nebulas and repelled from the regions of their formation with a tendency to be impelled by some kind of polarity 50 to 75 per cent. faster in the direction of the major axis of the ellipsoid than in a direction at right angles to that. This hypothesis also fits in well with the undoubted phenomenon of acceleration of a star's motion with age.

The section elected President E. O. Lovett member of the council, Professor F. B. Littell member of the sectional committee, and Dean H. T. Eddy member of the general committee. On recommendation of the sectional committee Professor E. B. Van Vleck, University of Wisconsin, was elected chairman of the section by the general committee.

G. A. MILLER,

Secretary of Section A

UNIVERSITY OF ILLINOIS

THE ASSOCIATION OF AMERICAN GEOGRAPHERS

THE eighth annual meeting of the association was held in Washington, December 28-30, 1911. Through the kindness of the National Geographic Society, the sessions were held in Hubbard Memorial Hall, and luncheon was provided for those in attendance.

The president, Professor Ralph S. Tarr, of Cornell University, presided, and gave the president's address. His subject was "The Glaciers and Glaciation of Alaska." Professor Martin read a memorial of Professor Christopher Webber Hall, who died on May 10, 1911. In addition to these addresses, thirty-six papers were read by members and by several others on invitation. Paper on subjects in meteorology were more numerous than at any previous meeting of the association.

On Friday evening the association met with the Geological Society of America to hear the address of its president, Professor W. M. Davis, upon the subject "The Relations of Geology and Geography." This was followed by a smoker given to both societies at the Cosmos Club by the Geological Society of Washington.

The first volume of the *Annals* of the association is now in press and will appear during the winter under the editorship of Professor R. E. Dodge. Announcement was made of the election of the following officers for the year 1912: *President*, Rollin D. Salisbury; *First Vice-president*, Marius R. Campbell; *Second Vice-president*, Isaiah Bowman; *Secretary*, Albert Perry Brigham; *Treasurer*, Nevin M. Fenneman; *Councillor for three years*, Lawrence Martin. The next annual meeting will be held in New Haven.

ALBERT PERRY BRIGHAM,
Secretary

THE SOCIETY OF AMERICAN BACTERIOLOGISTS

At the Washington meeting of the society from December 27-29, the following papers were presented:

Biochemical Problems in Bacteriology (president's address): F. P. GORHAM.

This address will appear in SCIENCE.

The Classification of the Streptococci by their Action upon Carbohydrate Media: C.-E. A. WINSLOW.

When Gordon first suggested the use of carbohydrate media for differentiating streptococci, it

seemed that this long-mooted problem was at last likely to be solved. The work of the last five years has, however, left matters in almost as confused a condition as ever, since different observers obtain such varied, and in some cases, conflicting results.

The author attempts to review in this paper the results of four recent American investigations, including 302 fecal streptococci, studied by Winslow and Palmer, 101 milk streptococci studied by Broadhurst, 65 throat cultures studied by Hilliard and 17 cultures from various sources examined by Bellinger, of Meadville College.

In all these cases the amount of acidity produced was determined by titration. The first point brought out is that the dividing line between fermenting and non-fermenting strains lies at about 1.2 per cent. acidity. The English results obtained by Gordon and Houston have been obtained by the use of litmus without titration, and if their solutions were not exactly neutral at the start, they must have classified as fermenting many organisms which really belong to the non-fermenting class. A careful comparison of the English results for particular groups shows, indeed, that they include a much greater percentage of positive records than the American ones.

Experience seems to indicate that systematic studies of the carbohydrate relations of the streptococci should be carried out by titration with phenolphthalein as an indicator. Media may be made up from meat extract (each batch checked by controls inoculated with *B. coli*) and adjusted to an initial reaction between neutral and .5 per cent. acid. Dextrose, lactose, saccharose, salicin, inulin, mannite and raffinose should all be used for diagnosis for the present at least, and titration may be made after cultivation for three days at 37° C.

When studied in this way, cultures producing over 1.2 per cent. acidity more than that initially recorded being considered positive, the media are acted upon (with occasional exception) in accordance with a definite order of fermentability, which is quite different from the order which prevails in the colon group. If only one carbohydrate is attacked that one is usually dextrose. Lactose and saccharose come next and particularly with fecal streptococci. Salicin is almost as commonly acted upon. Mannite is rarely attacked except by streptococci from milk and human feces, while raffinose is rarely attacked except by organisms from bovine feces. Inulin fermenters occur only abun-

dantly in milk. These facts correspond with the chemical relationships of the sugars, the monosaccharide and disaccharide being most readily attacked, next the glucoside, salicin, which breaks up into a simple sugar, while the more complex carbohydrates are less available. The streptococci form a more or less continuous series from those which attack no sugar at all to those which ferment all the carbohydrates tested. Occasionally a strain reacts with a substance lower in the series of fermentability while failing to do so in a sugar usually more available, but this is rare. Characteristic forms appear in the throat and in the feces of man and other animals, so that the method promises to prove of practical as well as theoretical value.

A Comparison of Streptococci from Milk and from the Human Throat: E. C. STOWELL and C. M. HILLIARD.

The present study of throat and milk streptococci was undertaken with the object of establishing a method for distinguishing between organisms isolated from the two sources. (The small number of strains examined (70) renders any present generalizations only tentative.)

The streptococci used were all isolated from fresh specimens in our laboratory by cultural and morphological examinations. Quantitative acid production was studied in six carbohydrate media; dextrose, maltose, lactose, saccharose, raffinose and mannite. The tubes were incubated at 37° and at 20 degrees for 72 hours. The maltose results are neglected in the present discussion.

Below 1.2 per cent. acid production at 37° is considered a negative reaction. All but four cultures on this basis fermented one or more of the carbohydrates; 83 per cent. may be placed in three groups according to the correlation of their capacity to ferment the media used. The following table shows this distribution:

Fermented	Per Cent. Throat Cultures	Per Cent. Milk Cultures
Dextrose only	22.2	6.3
Dextrose and lactose	20.4	38.0
Dextrose, lactose, saccharose ...	33.1	57.7

Grown at 20° the first reaction mode falls at 0.5 per cent. and on this basis the milk cultures fall into the same general groups as shown above, but the throat streptococci show 50 per cent. not to ferment at all, and 40 per cent. to ferment dextrose only.

A comparative study of the cultures isolated from sore, inflamed, or otherwise "abnormal" throats and from normal throats showed no essential differences; the reaction curves follow the same general contours throughout.

(No clue to the relationship of the forms studied was obtained from the morphology or staining reactions.)

Our work leads us to make three preliminary conclusions:

1. Streptococci from the human throat and from milk very generally ferment one or more of the sugars, dextrose, lactose and saccharose, attacking them most readily in the order named. They do not generally ferment raffinose or mannite.
2. The streptococci of the sore and the normal throat show no cultural differentiation in relation to the carbohydrates used. Virulence tests would perhaps have separated the two groups.
3. Milk streptococci are much more facultative than throat strains in relation to the temperature at which they are grown. This is, perhaps, the most valuable information obtained as a differential feature between chained cocci from the two sources.

A Study of Thirty-five Strains of Streptococci Isolated from Samples of Milk: GUSTAV F. RUEDIGER.

The paper points out that *Streptococcus lacticus* can be differentiated from *Streptococcus pyogenes* by means of blood-agar plates. *Streptococcus pyogenes* produces small colonies surrounded by a large zone of hemolysis, whereas *Streptococcus lacticus* produces green or grayish colonies with very little or no hemolysis.

Streptococcus lacticus has no sanitary significance, as it is found in nearly all samples of clean, soured, or fresh milk, and very often in the healthy milk ducts. *Streptococcus pyogenes*, on the other hand, seems to occur but rarely in milk and is indicative of the existence of an inflamed condition of the udder of the cow furnishing the milk.

A Biometrical Study of Milk Streptococci: JEAN BROADHURST.

This comparative study of carbohydrate fermentative reactions is based upon streptococci isolated from milk plates which were made in the routine milk examination by the New York Department of Health. One hundred strains were isolated, and as rapidly as purity was assured transferred to eight of the Gordon test media:

neutral red for reduction, milk for coagulation, and the following carbohydrates for acid formation: saccharose, lactose, salicin, inulin, mannit and raffinose.

Neutral red has since been discarded by Houston as not sufficiently diagnostic. Milk is apparently open to the same objection.

Only the six carbohydrates therefore remain for consideration. Houston used them all (and conferrin) in his milk tests, but secured qualitative results only. Quantitative ones have been recorded for 200 fecal (human, bovine and equine) strains by Winslow and Palmer for dextrose, lactose, raffinose and mannit.

Sugar-free broth was used, and the streptococci therefore began their growth with an initial acidity of 1.3 to 2.2 per cent. (deducted from all recorded results). After 72 hours' growth, titration (with phenolphthalein) showed the following results:

1. Non-fermenting and fermenting groups are found for each of the six carbohydrates tested. The dividing line lies near 1.5 per cent. (higher than among the fecal streptococci).

2. Streptococci ferment these carbohydrates in a large percentage of the strains: lactose, 74 per cent.; saccharose, 68 per cent.; salicin, 77 per cent.; inulin, 37 per cent.; mannite, 26 per cent., and raffinose, 13 per cent.

3. The amount of acid is remarkably large (highest in saccharose, 8.4 per cent.).

4. The reaction combinations observed are numerous, and therefore small: 4 groups of 10 or more strains, and 4 of 5 to 9 strains; these include about 75 per cent. of the strains.

5. These reaction groups are apparently not correlated with morphological characters.

6. The high records for acidity are even more remarkable when the initial acidity is considered.

DISCUSSION OF STREPTOCOCCI

W. L. Holman referred briefly to the Andrade indicator—acid fuchsin decolorized by sodium hydate—as used in the pathological laboratories in Pittsburgh. He spoke of the differential media for streptococci in use by them, viz., blood agar, lactose, mannit, salicin and inulin broth and laid particular stress on the fermentation or non-fermentation of the various carbohydrates, believing that of greater importance than the exact titration of acidity produced. The use of the hemolytic test he advocated as of great importance in separating two large groups of the streptococci.

A Study of the Diphtheria Group by the Biometric Method: M. E. MORSE.

This study was undertaken for the Boston State Hospital at the instance of Dr. E. E. Southward. The writer is greatly indebted to Professor C. E. A. Winslow for assistance.

The characteristics which were chosen as the basis of classification were:

- A. Morphology. The cultures of diphtheria bacilli were grouped as granular, segmented and those in which solid and small granular forms predominated.

- B. Vigor of growth.

- C. Chromogenesis.

- D. Quantitative determination of acidity in 1 per cent. dextrose, maltose, glycerin, saccharose and dextrin broth.

- E. Virulence (guinea-pig inoculation).

- F. Toxin production.

- G. Immunity reaction (fixation of complement and conglutination). This part of the work is still in progress, and will be reported later.

187 strains of Klebs-Loeffler bacilli, 76 of diphtheroids and 23 of Hoffmann's bacillus have been studied.

RESULTS. I. DIPHTHERIA GROUP

A study of the relationship between morphology and virulence shows that 61 per cent. of the granular cultures were virulent, and only 34 per cent. of the segmented cultures. The solid and small granular cultures were, with one exception, non-virulent.

The group of virulent diphtheria bacilli forms more acid in dextrose, maltose and dextrin broth, than does the non-virulent group.

There are forms sharing the characteristics both of the Klebs-Loeffler group and the diphtheroids.

II. DIPHTHEROID GROUP

The common diphtheroids found on the human body fall into three sub-groups.

Group A.—The so-called "Hoagbacillus." Medium-sized bacillus with solid, barred and wedge forms. On serum, a very heavy glistening salmon-pink growth. Ferments dextrose and saccharose always, maltose and glycerin infrequently; and never dextrin.

Group B.—Morphologically larger and thicker than "Hoagbacillus"; forms with clear-cut bars predominate. On serum, a heavy yellow, dry growth. Ferments dextrose, but not saccharose; usually maltose, glycerin frequently.

Group C.—Differentiated primarily by slow, scanty, colorless or white growth. Morphologically smaller than organisms of group *B*; thick, curved, with solid, barred and wedge forms. Ferments dextrose, always; saccharose usually, maltose and glycerin in 50 per cent. of cultures. The xerosis bacillus apparently belongs to this group.

CONCLUSIONS

1. The division of diphtheria bacilli into virulent and non-virulent varieties is justified by differences in morphology and degree of fermentative powers, and by the absence of intermediate grades of virulence, as shown by animal inoculations.

2. The common "diphtheroid" organisms found in the human body fall into three sub-groups.

3. *B. Hoffmann's* has no biological relationship either to the diphtheria bacillus or to the diphtheroids.

A Biometric Investigation of Certain Non-spore-forming Intestinal Bacilli: EUGENE C. HOWE.

Six hundred and thirty strains of intestinal bacilli were collected from stools of twenty-one individuals—mostly healthy men. These were subjected to the following quantitative tests: (1) Acid and gas formation in dextrose, lactose, saccharose, raffinose, levulose, mannite and dulcitol. (2) Acid production in milk. (3) Digestion of starch. (4) Production of indol from peptone. (5) Reduction of nitrates. (6) Gelatin liquefaction. (7) Morphology. (8) Motility.

The resulting data were analyzed statistically with the following conclusions to date relative to the non-gelatin liquefiers (540 strains):

1. Confirmation of the accepted view that motility has not systematic significance within the group "*B. coli* and closely related organisms."

2. Lack of classificatory value of amount of gas produced and "gas ratio."

3. Acid formation, a sounder criterion than production of gas.

4. Mannite, dulcitol and starch of little value in classification of this group, in connection with the other tests used. There is no correlation between the first three and the latter.

5. Indol, ammonia, and nitrite formation but slightly correlated with the general robustness of the organism and of little significance in classification within this group.

6. Dextrose, lactose, saccharose and raffinose constitute a natural *metabolic gradient*. Fermentation of any member of the series implies fermentation of members lower in the series.

7. On this basis there are two main groups of dextrose fermenting, gelatin-minus, non-spore-forming, intestinal bacilli and four sub-groups.

- I. (58%) { Dex. + Lact. + Sac. + Raf. + 1 (53%)
 { Dex. + Lact. + Sac. + Raf. — 2 (5%)
II. (42%) { Dex. + Lact. + Sac. + Raf. — 3 (41%)
 { Dex. + Lact. — Sac. — Raf. — 4 (1%)

The Green Fluorescent Bacteria of Maple Sap: H. A. EDSON and C. W. CARPENTER.

Green fluorescent bacteria are the most important agents in the deterioration of maple sap. These microorganisms feed upon the traces of protein present in the sap, but have little, if any, action upon the sugar. The sap becomes cloudy with more or less green color and produces an inferior quality of syrup and sugar.

Forty-two strains of this group of bacteria which were isolated from maple sap, together with five cultures of known species from Kral and one from Novy, were studied. The latter were: *B. fluorescens albus*, *B. fluorescens liquefaciens*, *B. fluorescens longus*, *B. fluorescens mesentericus*, *B. fluorescens tenuis* and *B. fluorescens putidus*. The chief differences observed in the entire series of cultures were in respect to the following characters: nitrate reduction; growth on synthetic media; gelatin liquefaction and casein digestion in milk; hydrogen sulphide production; temperature relations.

Thirty-three strains of the fluorescent sap bacteria agree closely with *B. fluorescens liquefaciens*; two strains resemble *B. fluorescens mesentericus* and seven strains are similar to *B. fluorescens tenuis*.

Bacterial Variation Due to Acidity and Flow in the Youghiogheny River at McKeesport, Pennsylvania: E. C. TRAX.

The germicidal action of drainage from coal mines, containing as it does free sulphuric acid and iron in solution, is indicated by its composition.

Experiments made by the Department of Health of Pennsylvania lead to the conclusion that "Mine water will prevent the growth of typhoid bacilli after the lapse of one hour, and will markedly limit the growth of colon bacilli so that they die off progressively and can not be cultivated after 24 hours."

The acidity of the water in the Youghiogheny River is caused by the acid mine drainage, an immense quantity of which is discharged into the river and its tributaries. The reaction of the

water at McKeesport ranges from 20 parts per million alkaline during high stage of water to 39 parts acid at low stage, and the bacterial life of the stream is directly affected thereby.

The monthly averages of bacteria per cubic centimeter, acidity and height of river, are given below for the year 1910:

Month 1910	Av. Acidity (a)	No. Bacteria per c.c. (b)	Stage of River (c)
January	11	31,000	5.3
February	37	20,000	3.4
March	36	21,000	3.1
April	52	12,000	1.8
May	23	2,000	1.6
June	6	6,500	3.3
July	65	205	0.7
August	182	9	0.1
September	113	97	— 0.2
October	240	240	— 0.1
November	176	160	0.1
December	29	2,400	2.0

(a) Acidity to methyl orange in parts per million.

(b) 48 hours' incubation at 20° C.

(c) Gauge height in feet at West Newton.

It can be stated in a general way that the bacterial numbers vary with the gauge height of the river and inversely as the acidity. The acidity of the water is controlled by the conditions of rainfall, run off and flow, inasmuch as these are the factors which affect the dilution of the mine drainage. Allowing for the natural fluctuation of bacterial life in a flowing stream, the presence of the mine water is responsible for a considerable reduction at all times except during floods, when the water is alkaline, while during high acidity the effect approaches sterilization.

Water Sterilization by Emergency Chlorinated Lime Treatment Plants: RALPH E. IRWIN.

When emergencies call for the immediate sterilization of a public domestic water supply, temporary treatment apparatus may be constructed by using barrels to mix and feed chlorinated lime into the suction main, suction well or point where the water passes and thorough mixing is insured.

The solution may be mixed and settled in one barrel and fed from another *via* regulating valves. With this crude device water from large and small streams, wells and springs have been disinfected and communities protected from water-borne disease.

Two examples are given showing the bacteriological results obtained by treating similar spring waters that were infected and had caused epidemics of a water-borne disease.

The first spring furnished 1 to 1.5 million gallons daily and was under municipal control where political protection was given inefficient employees. During a period of 115 days, bacteriological determinations were made showing the total number of bacteria and *B. coli* present in 85 samples of untreated water from the spring, 70 samples of treated water as it left the pump and 75 samples from taps about the city. On 8 days samples were obtained showing *B. coli* in such large numbers that it was evident little, if any, lime was being added. The results as a whole show, however, that the prescribed 6 to 8 pounds of high-grade chlorinated lime per million gallons was sufficient to sterilize the water if added as directed.

The second spring furnished 3 to 3.5 million gallons daily and was under strict corporate control with employees obeying orders. During a period of 103 days, bacteriological determinations were made showing the total number of bacteria and *B. coli* present in 36 samples of untreated water from the spring and 36 samples of treated water from taps on the pump or distributing system. The treated water showed excellent reductions in total counts in every instance, and *B. coli* were absent throughout the period of treatment.

With a crude device such as described in the hands of efficient workmen during emergencies, creditable results may be obtained and valuable protection given.

The Distribution of Bacteria in Certain New York Soils: H. J. CONN.

Extensive work for two years with a certain clay loam at Ithaca has resulted in the isolation and study of about five hundred cultures. These cultures have been classified into thirty-four types, which are essentially species. Grouping these types into six easily distinguished classes, their relative frequency can be thus stated:

5-10 per cent. spore-producing liquefiers; large rods (*e. g.*, *B. subtilis* and *B. mycoides*).

5-10 per cent. non-spore-producing, rapid liquefiers; small rods with polar flagella (*e. g.*, *Ps. fluorescens*).

40-70 per cent. non-spore-producing, slow liquefiers; short rods, immotile (except one with polar flagella); growing very poorly in ordinary laboratory media.

Ca. 10 per cent. non-spore-producing, non-liquefiers; short rods, immotile or with polar flagella.

Trace. Micrococci, like the last group physiologically.

15-45 per cent. Actinomycetes.

Of these six groups all are strict aerobes except a few in group 1; almost without exception none produce gas from sugars; while acid production, although common, is always very weak.

Each group comprises about seven or eight types, except the last two, in which there are but one or two types.

This year forty more cultures have been isolated from four other soils elsewhere in the state. Two were clays, one a silt and the other a sand. With few exceptions these cultures seem to be the same kinds as those previously studied, although the relative frequency of the types is different. This suggests that there is a characteristic bacterial flora of soil. Accordingly, an intelligent comparison of soils demands the development of a technique to determine the relative abundance of the various kinds of organisms.

Soil Organisms which Destroy Cellulose: KARL F. KELLERMAN and I. G. MCBETH.

Our knowledge of cellulose destruction in soils is inadequate. Omeliansky's conclusions that cellulose is destroyed only under anaerobic conditions and gives rise either to hydrogen or methane are erroneous.

Two species of cellulose-destroying and five species of contaminating bacteria were isolated from Omeliansky's hydrogen culture, and one cellulose-destroying and two contaminating forms from his methane culture; none of the three species showed any resemblance to Omeliansky's hydrogen or methane ferments. In addition to the species isolated from Omeliansky's cultures eleven other species have been isolated from various other sources, one of which belongs to the thermophile group.

Contrary to Omeliansky's observation that cellulose-destroying bacteria do not grow upon solid media, most of the species isolated were found to grow readily upon such media as beef agar, gelatin, starch, potato and dextrose. Some of them have the power to liquefy gelatin. Although several of these organisms were isolated under anaerobic conditions, they grow equally well or better in the presence of air, which shows that the destruction of cellulose by bacteria is an aerobic rather than an anaerobic process.

It is usually supposed that filamentous fungi

are of little importance in agricultural soils; these investigations show them to be at least as important as bacteria in destroying cellulose. About seventy-five species of molds have been isolated representing a large number of genera; species of *Penicillium*, *Aspergillus* and *Fusarium* are perhaps most numerous.

In the destruction of pure cellulose either by bacteria or molds in synthetic media the associative action of organisms which presumably have no cellulose-dissolving enzymes frequently stimulates the growth of the cellulose organism and increases its destructive power.

Nitrates in Soils: F. L. STEVENS.

Nearly all text-books assert that nitrates are the chief source of nitrogen supply for green plants. Recent experiments throw doubt on this assertion. Attention was called to the need of tests bacterially and chemically controlled, conducted under natural conditions, to determine what forms of nitrogen are most readily available to the leading crop plants. Nitrification and denitrification were discussed. In particular question was raised as to the influence of organic matter mixed with nitrates in fertilizers (a common practise) upon loss by denitrification. Stress was laid upon the need of conducting tests in soils, not in solutions.

Why do some Soils Nitrify Organic Nitrogenous Substances and the Ammonium Salts of Organic Acids Faster than they do Ammonium Sulphate or Ammonium Chloride? J. C. TEMPLE.

Of 26 Georgia soils tested for nitrification, 24 were found to nitrify tankage more readily than ammonium sulphate, in some cases the amount of nitrate recovered from tankage was ten times that recovered when ammonium sulphate was the source of nitrogen. Tankage, cotton-seed meal, cowpea vines, gelatin, peptone, asparagin, urea, ammonium citrate, ammonium oxalate, ammonium tartrate, ammonium bicarbonate and ammonium hydrate were nitrified faster than ammonium sulphate or chloride. This condition was not due to the nature of the nitrifying organism in the soil, as the same thing held true when the nitrifying organisms were supplied as pure cultures, obtained from a number of sources. When calcium carbonate was added to the soil, ammonium sulphate was nitrified as well as any of the other substances.

The explanation offered for this condition was that these soils (all of the Cecil group) were acid, and that the soil organisms decomposed the substances of organic origin in a way that more ammonia than acid was produced, thus correcting

the acidity and bringing about a condition favorable for the growth of the nitrifying organisms. When ammonium sulphate or ammonium chloride was added to the soil there was no chance for a similar decomposition and the soils remained acid.

Bacteriological Studies of the Fixation of Nitrogen in Certain Colorado Soils: WALTER G. SACKETT.

The power to fix atmospheric nitrogen is a property common to many cultivated Colorado soils.

This power is not confined to the fixation of nitrogen in solutions, but is manifested in soils as well.

"The rate of fixation of nitrogen obtained is sufficient to account for the nitrates found in the soil provided that it is nitrified. The rate of nitrification obtained is sufficient to account for the formation of the nitrates found in most cases, if not all of them."

The nitrates formed are sufficient to destroy all vegetation, in one case amounting to 172 tons per acre in the surface five inches.

The nitrogen-fixing power is not confined to any geographical locality or class of soils, however, the adobe shale soils, both in a raw state and when newly cultivated, possess little, if any, nitrogen-fixing power.

Excessive nitrates either destroy or greatly attenuate the nitrogen-fixing flora of a soil.

A limited amount of soil nitrate does not seriously affect the nitrogen-fixing power of a soil.

Azotobacter chroococcum appears to be the dominant nitrogen-fixing organism in the soils studied.

The dark brown color of the niter soils is due, in a large part, to the pigment produced by *Azotobacter chroococcum*.

Given a source of energy, the nitrate is the limiting factor in the production of the brown color.

In the presence of nitrates, *Azotobacter chroococcum* develops a chocolate brown to black pigment; nitrites, in certain amounts, produce similar results, but to a less degree; nitrogen as NH_4Cl , $(\text{NH}_4)_2\text{SO}_4$, asparagin, and peptone has no effect upon this function.

The highly colored extracts obtained from certain niter soils suggests that the pigment of *Azotobacter chroococcum* may be soluble in the alkaline soil waters.

Excessive soil moisture, by interfering with the growth of *Azotobacter chroococcum*, prevents the formation of the brown color on the soil, and makes the fixation of atmospheric nitrogen impossible.

Excessive irrigation, too diligent cultivation and the alkaline reaction of our soils appear to favor unduly the growth of *Azotobacter*.

This paper is published in full as Bulletin 179 of the Colorado Experiment Station, Fort Collins, Colorado.

The Movement of Nitric Nitrogen in Soil: ROBERT STEWART and J. E. GREAVES.

In the work which has been conducted for eight years at the Utah Experiment Station upon the influence of irrigation water upon the production and movement of nitric nitrogen in the soil, there has been observed a variation in the nitric nitrogen content of the soil and the concentration of the soil solution with the water applied, the crop grown and with the season.

The soil upon which these investigations have been conducted is ideally adapted both chemically and bacteriologically to support a rapid bacterial action, yet the amount of nitric nitrogen present to a depth of ten feet does not exceed three hundred pounds per acre.

Deposits of nitrates do occur in the country rock in widely distributed areas in western America.

The careful analytical work reported by Dr. Headden on the composition of Colorado soils indicates a close relationship between the nitric nitrogen and chlorine content of these soils, indicating clearly a common origin of these two elements.

The Present Status of Soil Inoculation: KARL F. KELLERMAN.

The method of pure-culture inoculation is less certain than the use of soil from old well-inoculated fields, but has, however, the advantage of cheapness and greater ease of transportation and application, as well as the important advantage of the absence of introducing weeds and plant diseases. The crown-gall disease of fruit trees is the most conspicuous example of disease which may be disseminated by soil transfer.

Reports received from farmers who have conducted inoculation tests with cultures distributed by the Department of Agriculture during the past seven years give an average of 76 per cent. success and 24 per cent. failure, if only those reports are considered that make possible some determination regarding the action of cultures. If previously inoculated fields, crop failures and such other doubtful cases are included with the failures our percentage of success for this same period is reduced to 38.

The organism producing nitrogen-fixing nodules on the roots of legumes has been isolated and cultivated since 1903; di Rossi's contention that the proper organism had not been isolated prior to his work in 1907 appears without foundation.

By a new technique it has been possible to stain the flagella of this organism. Instead of bearing a single polar flagellum it is supplied with several peritrichic flagella. The proper designation of this organism, therefore, is *Bacillus radiclecola*.

The Persistence and Vitality of Bacteria on Alfalfa Seed: M. J. PRUCHA.

The seeds of the common farm crops such as wheat, corn, peas, alfalfa, etc., are extremely difficult to sterilize without killing the seed. It has also been shown that the bacteria of disease are carried on beans and corn. It is important to know to what extent bacteria may persist on the seed.

The following results were obtained from a quantitative and qualitative study of alfalfa seeds.

Nineteen samples, grown and collected in 1909, from 11 different states, have been studied for two years.

On fresh seed the germ content varied from 16,000 to 12 per seed. With age the germ content decreases. A typical sample which when fresh had 7,780 per seed, when two years old gave 340 bacteria per seed.

Simultaneous platings were made from the 19 samples and representatives of each apparent group were determined according to the Society Card.

Of the 84 different group numbers determined, 35 were *Bacillus*, 21 *Bacterium*, 19 *Pseudomonas*, 1 *Streptococcus* and 8 Yeast. About one third of these forms were widely distributed and many of them very persistent on the seeds. Of the 84 groups, 68 were chromogenic, yellow being much the more common. The samples from semi-arid regions gave especially brilliant colors. But 8 of the 84 groups were spore formers and the spore formers represent only about one fifth of the forms present at the end of two years.

The reduction in numbers of bacteria, with age, is due to a decrease within each group, gradually the less numerous groups disappear. At the end of two years the most widely-distributed and most numerous group is *Bact.* 211.3332533—a non-spore former.

This work will appear as a bulletin of the New York Agricultural Experiment Station, Geneva, N. Y.

The Behavior of Pseudomonas radiclecola in the Soil: B. M. DUGGAR and M. J. PRUCHA.

This paper is in the form of a preliminary report on (1) the effects of conditions, especially drying, on the vitality of the germ, and (2) the multiplication of the germ in soil under the influence of various factors. The results indicate that there are certain undetermined factors which seem to affect vitality after drying, yet it seems certain that after the rapid or sudden drying-out of soil cultures there remains a considerable number of living organisms, the existence of which may be determined either by the direct plate method, indirect plating (after inoculation into bouillon) or host inoculation. When soil cultures are directly and rapidly dried out the number of organisms found by the plate method may be no more than about one twentieth of those present when the drying began. This, however, relates to excessive drying. Where the drying process is less complete, the number remaining alive is much greater, and the life of the germ extends over a considerable period of time.

Cultures of this germ in sterile soil (clay loam) after five days gave about 160,000,000 organisms per gram, which is considerably more than the number found per c.c. in a control bouillon culture. In certain experiments, sterile and unsterile soils were mixed in various proportions, and the mixed material thoroughly inoculated and compared with the check in sterile soil. The addition of the unsterile soil inhibits multiplication of the legume germ as the amount of unsterile soil is increased.

Casein Media Adapted to Milk Analysis: S. HENRY AYERS.

CASEIN AGAR

Preparation of One Liter

Casein Solution	Agar Solution
300 c.c. distilled water	500 c.c. distilled water
10 gm. casein (Eimer and Amend c.p. casein prepared according to Hammersten)	10 gm. agar

7 c.c. normal sodium hydroxide.

After dissolving casein make up to 500 cubic centimeters.

To 300 c.c. water (distilled) add

10 gm. casein (Eimer and Amend c.p. casein prepared according to Hammersten)

and 7 c.c. normal sodium hydroxide.

Dissolve casein by heating to boiling. It is desirable to let this solution stand for several hours to get a perfect solution. This is not necessary, however. Make up volume to 500 c.c. and bring the reaction of the solution to between + 0.1 and + 0.2 Fuller's scale. Do not allow this solution to become alkaline to phenolphthalein or over - 0.2. If the casein is weighed accurately and the normal solution accurate the reaction will be about + 0.2.

The agar solution is prepared by dissolving 10 gm. agar in 500 c.c. of water. Both casein and agar solution should be filtered, then mixed. Tube and sterilize in autoclave under pressure for 20 minutes; then cool the tubes quickly in cold water or ice water. The final reaction of the medium will be about + 0.1 Fuller's scale. If the medium is alkaline, the bacterial growth will be restricted. If the medium is more than + 0.1 some of the casein may be precipitated during sterilization. The casein agar should be clear and almost colorless when poured in a Petri dish. Sometimes the casein will be slightly precipitated during sterilization on the cooling, but it is of no consequence, since on pouring into plates the precipitate on account of its finely divided condition becomes invisible.

The study of the bacterial growth on casein agar and infusion agar shows the following points:

1. The 24 hours' count at 37° on casein agar was almost always lower than on infusion agar when raw milk is being examined. When pasteurized milk was examined the casein plates showed a higher count in 37 per cent. of the samples.

2. After 6 days' incubation at 30° C., out of 50 samples of raw milk plated, 44 per cent. of the samples showed higher counts on casein agar. With 50 samples of pasteurized milk, 78 per cent. of the samples showed a higher count on casein agar.

3. From a study of the bacteria from about 50 samples of both raw and pasteurized milk it seems that acid-forming bacteria do not develop quite as well on casein agar. It does, however, favor the growth of the alkali formers, the peptonizers and inert bacteria.

4. The number of peptonizing bacteria in a sample of milk may be determined directly from a casein agar plate. After counting the plate it should be flowed with *N*/10 lactic acid; this causes the precipitation of the casein, giving a white opaque plate except where the casein has been dissolved about a colony of peptonizing bacteria.

There is then left a clear zone around the colonies of peptonizing bacteria which enables one to determine their numbers in the sample of milk under examination. It has been found from a study of a large number of samples that this method of determination is accurate.

Sugars may be added to the casein agar or the casein solution may be used as a liquid medium without agar. It is believed that these media using casein will be of considerable value in bacteriological milk analysis.

The Analysis of the Gases Produced by One Hundred Cultures of Bacteria: WM. MANSFIELD CLARK.

The purpose of these analyses was to furnish data for the identification of gas-producing bacteria isolated from dairy products.

The bacteria were grown in a special form of culture bulb, evacuated with a mercury pump after inoculation, sealed up and incubated seven days at 30° C. The culture medium was a bouillon containing 1 per cent. dextrose. Exactly 5 c.c. of this was used in each bulb.

The collection of the gas was made with an Antropoff mercury pump and the analyses were made with special burettes and Hempel pipettes adapted for accurate analyses of small volumes.

The majority of the cultures analyzed gave a ratio of CO₂, H₂ similar to that of *B. coli communis*. Certain other distinct ratios were found. These depend in large measure upon the volume of CO₂, the hydrogen tending to remain constant. Certain other relationships are suggested tentatively, pending further investigation.

A Study of Gas-forming Bacteria in Milk: L. A. ROGERS and B. J. DAVIS.

Cultures of gas-forming organisms have been isolated from milk and other dairy products obtained in various parts of the country. These have been studied with special reference to the relation between certain physiological reactions, as the fermentation of carbohydrates and the amount of gas and ratio of H₂ to CO₂. Plotted on the frequency basis the H₂:CO₂ ratio has given four more or less distinct nodes, one at the ratio 1:1.1, one at 1:1.8, one at 1:2.2, and one at 1:2.7.

Arranged in a similar way, the amount of gas produced under given conditions shows nodes at 4 c.c., between 7 and 8 c.c. and 17 c.c.

Proper classification of the cultures shows a close correlation between the H₂:CO₂ ratio and the amount of gas.

The gas ratio is further correlated in some cases with the fermentation of certain carbohydrates.

The group giving a ratio of 1:1.6 to 1:2.0 shows a distinctly greater ability to ferment saccharose, raffinose and starch than the group giving the ratio 1:1.1. It is probable that these tentative groups are somewhat heterogeneous and that further refinement by the use of new test substances will bring out sharper distinctions.

The Bacteriology of Cheddar Cheese: E. G. HASTINGS and ALICE C. EVANS.

Will appear soon in bulletin form jointly from the Dairy Division, Bureau of Animal Industry, U. S. Department of Agriculture, and the Wisconsin Experiment Station.

Some Actions of Microorganisms upon the Constituents of Butter: CHARLES W. BROWN.

For this work one lot of cream, divided into two parts—one part pasteurized at 160° to 170° F., the other not pasteurized—was churned and the butter placed in storage at -3° F. to +3° F. Of the 88 different species of microorganisms, not including molds or the higher bacteria, isolated from this butter 57 are bacteria (cocci, bacilli or spirilla) and 31 are yeasts. It was noticed:

1. That 24 of the bacteria and 15 of the yeasts will grow on 12 per cent. salt at 20° C. Four of these bacteria and six of these yeasts grow well on 12 per cent. salt at 6° C.

2. That the ratio of the number of species of liquefying bacteria to the number of non-liquefying bacteria isolated from ordinary agar is the same as the liquefying to the non-liquefying isolated from 12 per cent. salt agar.

3. That 12 per cent. of salt has a much more inhibitive action upon the species of liquefying yeasts than it does upon the non-liquefying.

4. That the lactose in both the pasteurized and unpasteurized butter decreased from 0.315 per cent. and 0.325 per cent. to 0.285 per cent. to 0.290 per cent., respectively, in 428 days.

5. That 50 per cent. of the decrease in lactose took place within the first 10 days.

6. That when the butter was taken from storage at the end of 428 days and placed at room temperature very little further decomposition of lactose occurred.

7. That the soluble nitrogen recorded in percentage of the total nitrogen in the butter increased in 428 days from 6.25 per cent. and 7.69 per cent. to 6.29 per cent. and 7.84 per cent. for the pasteurized and unpasteurized, respectively.

8. That the acidity of the pasteurized butter remained constant while that of the unpasteurized increased from 25.5° to 33.9° (Fuller's scale).

9. That when the growth upon synthetic agar was compared with the growth upon the same agar to which 1 per cent. butter fat—freed from impurities by melting and decanting—was added, 9 species of the bacteria showed a more luxuriant growth in the presence of fat, 11 were inhibited and 37 were indifferent; while 20 of the yeasts grew more luxuriant, 5 were inhibited and 6 indifferent.

A Bacteriological Study of the Milk Supply of Washington, D. C.: J. J. KINYOUN and L. V. DEITER.

A series of bacteriological examinations of the milk supply of Washington, D. C., were continued over a period of 14 months beginning in September, 1910, and ending on November 1, 1911. The objects of these examinations were to ascertain as near as was possible the actual conditions of the milk supply during this period so as to be able to formulate some means of its improvement.

Samples of milk were examined in accordance with the rules and methods prescribed by the Laboratory Section of the American Public Health Association and in addition thereto special methods were employed for the detection of the colon group.

The result of this study was that the milk supply of Washington was on the whole very unsatisfactory and was capable of a great improvement.

Nearly all the raw milk arriving in the city by rail had a very high bacterial content, the average for all samples for the 14 months was 9,300,000 and in no instance was it below 1,000,000.

55 per cent. of the samples contained both colon and streptococci. The close parallel between these two groups is looked upon by the writers as a sure indication of dirty collection and imperfect handling.

The examinations of the "pasteurized" milk as it is purveyed is far from satisfactory. This condition was due in a great measure to the imperfect way in which the process was applied, or to the attempts of the dealer to pasteurize an old or a dirty milk in order to sell it.

It has been clearly demonstrated by this study that a great amount of the milk as supplied is collected under unfavorable conditions, and is imperfectly or carelessly handled.

The Bacteriological Improvement of a Milk Supply by other than Laboratory Means: H. A. HARDING.

Bacterial studies have shown that the essentials for the production of cleaner milk are:

1. The utensils and the cow and her surroundings during the milking process must be as clean as possible.

2. The milk must be cooled as promptly and as thoroughly as possible. The problem of the bacteriologists becomes: how to induce the production of milk in accord with these essentials.

Attempts at securing this by establishing maximum permissible germ contents are undesirable because:

1. We lack data for establishing the point at which germ content begins to menace the public health.

2. We lack technique for determining the germ content of milk with an accuracy demanded by such legal enactment.

3. Such enactment has slight educational value because it can not be readily translated by dairymen into terms of their dairy practises.

The bacteriologists must translate the results of their studies into terms of dairy practises, and this translation may well take the form of a *score card*. If the valuation in this score card is correct the resulting score is an accurate measure of the relative desirability of the dairy product.

Such a mathematical expression is valuable because it facilitates buying and selling milk on the basis of quality.

In Geneva, N. Y., where the Cornell score card was taken voluntarily by the milkmen as a basis of payment according to quality:

"Poor" milk, originally one third of the total supply, decreased sharply and disappeared after three years.

"Medium" milk, originally about two thirds of the supply, decreased sharply and disappeared after three years.

"Good" milk, originally only five per cent. of the supply, quickly displaced the two lower grades.

"Excellent" milk, previously unknown, was twelve per cent. of the supply after three years.

The details of this work are given in New York Agricultural Experiment Station Bulletin 337.

This complete transformation of a municipal milk supply was accomplished at a cost to the city of \$500 per year.

The dairymen are desirous of furnishing the highest grade of milk for which they can get a price proportionate to the quality. The first necessity is a definition of the desired quality in terms which the dairymen can clearly understand. The dairy score card is the most promising attempt in this direction. The second necessity is the establishing of definite market grades of quality in milk, so that the consumer can purchase intelligently and create a commercial demand for a better article. The action of the New York Health Department in this direction is commendable.

Any permanent improvement in a municipal milk supply must rest upon conditions which make it more profitable to furnish a cleaner milk than to furnish a dirtier one.

The Principle of Vacuum Cleaning as Applied to Dairy Cows: G. L. RUEHLE.

The Object.—A comparison of the results obtained by a vacuum cleaner and by hand cleaning of cows. The points considered were (1) the effect on the germ content of the milk, (2) the time consumed.

The Method.—Two cows were cleaned each night by each method. The groups were alternated on succeeding nights. Observations were made on 22 nights.

The general average for hand cleaning was 669 per c.c., and for machine cleaning it was 1,145 per c.c.

Time Consumed.—Owing to the small number of cows per day, measurements of the time required by each method were not satisfactory. However, it was plain that the vacuum cleaning consumed more time than hand cleaning. As vacuum cleaning of cows took more time and gave poorer results, it does not commend itself to dairy practise.

EFFECT ON GERM CONTENT

	Germ Content per c.c. from Machine and Hand Cleaned Cows							
	Cow No. 1		Cow No. 2		Cow No. 3		Cow No. 4	
	Hand	Machine	Hand	Machine	Hand	Machine	Hand	Machine
No. samples.....	10	12	10	12	11	11	11	11
Totals.....	20,765	26,459	1,479	1,624	2,541	16,309	3,305	8,297
Averages.....	2,077	2,205	148	35	231	1,483	300	754

Results will appear in a Bulletin of the New York Agricultural Experiment Station.

Suggestion of a New Method of Stating Composite Results of Bacterial Milk Counts: ERNEST C. LEVY.

Statement of the "average bacterial count" of milk samples in any city is of comparatively little value on account of the influence of a few samples, or even a single sample, of very high bacterial content.

The most approved method of statement of results has therefore been to give the number of samples, and the percentage of samples, falling in each of certain more or less arbitrary groups or classes, in the following manner:

(A) Class	No. of Samples	Per Cent. of All Classes
Under 10,000	25	16.7
10,001 to 50,000	73	48.6
50,001 to 100,000	37	24.7
100,001 to 250,000	9	6.0

If we apply this method to the hypothetical 150 samples given under (A) we get the following:

(C) Class	Rating Figure	No. of Samples in Each Class	Product
Under 10,000	100	25	2,500
10,001 to 50,000	90	73	6,570
50,001 to 100,000	75	37	2,775
100,001 to 250,000	50	9	450
250,001 to 499,000	20	3	60
Over 500,000	0	3	0
Totals	150		12,355
"Bacterial index"			82.4
250,001 to 500,000	3		2.0
Over 500,001	3		2.0
Total	150		100.0

This method, while of more real value than a mere statement of average count, is too cumbersome. In order to get around these difficulties, a new method of statement—the "bacterial index"—is suggested. To each of the groups above shown a rating value is given, as follows:

(B) Class	Suggested Rating Figure for Raw Milk
Under 10,000	100
10,001 to 50,000	90
50,001 to 100,000	75
100,001 to 250,000	50
250,001 to 499,000	20
Over 500,000	0

The bacterial index thus arrived at takes into account the number of samples falling in each class, but at the same time enables us to state our results in a single figure, and this figure is not unduly influenced by exceptional samples. The method itself is believed to be of real value, but the rating figures given are only suggestive and, if the method is adopted for general use, proper rating figures should be agreed upon after careful consideration by some competent body of bacteriologists.

In applying the method of statement to samples of pasteurized milk, a different set of rating figures should be used. We know less about this than about raw milk, but the following ratings are given as illustrative:

(D) Class	Suggested Rating Figure for Pasteurized Milk
Under 100	100
101 to 500	90
501 to 1,000	75
1,001 to 5,000	50
5,001 to 9,900	20
Over 10,000	0

An additional advantage of using the bacterial index in stating results for pasteurized milk samples is that we get around the danger of having misleading comparisons made between the bacterial counts of raw and pasteurized milk. Instead of this, with proper rating figures for each kind of milk, we can compare any group of raw samples with ideal raw milk and any group of pasteurized samples with ideal pasteurized milk.

The Control of Pasteurized Milk by Physical and Bacterial Standards: WILLIAM ROYAL STOKES and FRANK W. HACHTEL.

The article after emphasizing the importance of the control of the pasteurization of milk and of milk after it has been pasteurized described the bacterial reduction obtained through the pasteurization of milk by means of the so-called "slow" and "rapid" methods. It then mentioned the physical and bacteriological standards for the control of pasteurization which were established by Koehler and Tonney, of Chicago. The minimum temperature requirements for the continuous or rapid type of pasteurization are 160° F. (71° C.) for one minute, and for the slow or "holding" method 140° F. (60° C.) for twenty minutes. These requirements have been adopted

since the tubercle bacillus is destroyed under such conditions, and this is considered as a sanitary index of efficient pasteurization. As the bacteriological standard they require that there should be a reduction of 99 per cent. of the bacteria after pasteurization as compared to the raw milk, but this is not strictly applied if the bacteria are less than 100,000 per c.c. Koehler and Tonney have also shown the percentage of reduction during the various stages of pasteurization by the rapid method varying between 150° F. and 164° F., and by the slow method varying between 143° F. and 150° F. The bacterial count even in the bottled milk at the end of both processes showed a bacterial reduction of about 99.5 per cent., with the exception of the bottled milk in the rapid method, which only showed a reduction of 98.75 per cent.

This article, then citing the work of the authors, shows an average reduction by pasteurization in Baltimore of 99.4 per cent. by the rapid method and 99.1 per cent. by the slow method. There were fewer counts made of the rapid method (96) than by the slow method (146), and the counts of the raw milk by the rapid method were much higher.

The writers have also studied the percentage of cases in which the colon bacillus was present before and after pasteurization in 1 c.c. or in 1/10 c.c., and their results were as follows:

PERCENTAGE OF CASES IN WHICH COLON BACILLI WERE PRESENT BEFORE AND AFTER PASTEURIZATION

Rapid Method					Slow Method				
Number of Examinations	Colon Bacillus Present Before Pasteurization in 0.001 c.c.		Colon Bacillus Present After Pasteurization in 1 c.c.		Number of Examinations	Colon Bacillus Present Before Pasteurization in 0.001 c.c.		Colon Bacillus Present After Pasteurization in 1 c.c.	
96	45	46.8 %	48	50.0 %	146	86	58.9 %	87	59.5 %
Number of Examinations	Colon Bacillus Present Before Pasteurization in 0.001 c.c.		Colon Bacillus Present After Pasteurization in 0.1 c.c.		Number of Examinations	Colon Bacillus Present Before Pasteurization in 0.001 c.c.		Colon Bacillus Present After Pasteurization in 1 c.c.	
33	22	66.6 %	7	21.2 %	93	68	73.1 %	42	45.1 %

The article then considers the recontamination of pasteurized milk, showing by the work of Koehler and Tonney that while the average count from a large number of freshly pasteurized milks was only 125,000, yet the average count from pasteurized milk one day old was 602,000 bacteria per cubic centimeter. Some of this milk showed counts varying between 1,000,000 and 4,800,000 per cubic centimeter. These authors think that this recontamination can best be obviated by a strict enforcement of a maximum standard for the temperature of milk of 50° C.

The conclusions are that the physical and bacterial standards of Koehler and Tonney are reasonable, and that the question of an additional safeguard establishing a maximum amount in which colon bacilli can be present in pasteurized milk is still open for debate.

Recent Developments in Pasteurization of Milk for a General Market: EDWIN HENRY SCHORER.

Pasteurization is employed legitimately to destroy pathogenic organisms of diseases transmitted through milk and to preserve milk so that it may be transported when properly refrigerated to localities where fresh milk is not obtainable. The process is used fraudulently to give low bacterial count to dirty milk, a redemption process, and to make milk keep in a manner similar to that of carefully obtained milk. In any event the process depends on heating milk to a temperature for a sufficient period of time to destroy the offending microorganisms. For fraudulent purposes it is only essential that a large percentage of bacteria be destroyed, while if milk is to be rendered free from possibility of causing infection, it is imperative that all pathogenic organisms be killed.

The entire process is based on scientific investigation, but unfortunately the results obtained in the laboratory are not obtained in the pasteurization of milk for the market. Pasteurization of

market milk must either be done in the bulk before bottling and capping or else in sealed bottles. Bulk pasteurization does not prevent reinfection and pasteurization in the bottle is expensive and time consuming.

While the primary object of the pasteurization of milk should be to destroy pathogenic bacteria, determination of the accomplishment of this object is a relatively difficult and slow process. For this reason the reduction in numbers of bacteria in milk is taken as evidence of efficiency of pasteurization. It is generally claimed that pasteuriza-

tion kills the lactic acid organisms and leaves the spores of peptonizing and putrefying bacteria. In the United States, however, pasteurized market milk coagulated sooner than does certified milk and peptonization occurs more frequently in the best grades of raw milk than in pasteurized market milk.

It can not be hoped that pasteurized dirty milk can be made as good as pasteurized clean milk, nor can a uniform product be expected as the result of pasteurization of market milk. While the higher grades of raw milk quite consistently have a low bacterial count, still they show a marked variation in flora. This same variation is observed in pasteurized market milk.

The technique in the laboratory does not prevail in the dairy and while pasteurization in sealed bottles can be made to represent laboratory methods, pressure for time may lead to over- or under-heating and shortening of the length of time of pasteurization. While heating to 140° F. for twenty minutes is sufficient in the laboratory to destroy pathogenic organisms, commercial conditions and mechanical devices are such that pasteurization should be carried on at a higher temperature and for a longer period of time.

The most efficient method of pasteurization is that under official supervision, controlling the quality of the milk pasteurized, pasteurization in the sealed bottle at 145° F. for thirty minutes, allowing at least thirty minutes to heat the milk to the pasteurizing temperature, and labeling such milk properly. This will insure sufficient temperature to destroy pathogenic bacteria, will inactivate the ferments but little, leave a good cream line and give a preferred milk.

The Bacterial Content of Oysters in the Shell in Storage: G. W. STILES.

Samples of oysters in the shell were taken from known localities during the months of November, 1910, and February, 1911, and placed in storage at a temperature of 39° F. Bacteriological analyses were made on five oysters constituting a single sample at various intervals ranging from one to 29 days. The usual technique for oyster work was observed for making the cultures. The oyster shells were well scrubbed in running tap water, their beaks briefly immersed in boiling water, and, with sterilized forceps and knife, the liquor removed from the shell into five sterilized petri dishes, one for the liquor of each oyster.

Definite quantities of 1 c.c., 0.1 c.c. and 0.01 c.c. from each oyster were planted into Durham fer-

mentation tubes containing lactose peptone ox bile. Dilutions of one to one hundred, one to one thousand, one to ten thousand, etc., were planted in duplicate on agar plates and incubated at 20° C., and 37° C., respectively, for three days.

The results obtained from the fermentation tests were expressed according to the suggested score of the Committee on Standard Methods of Shellfish Examination (*Journal of American Public Health Association*, Vol. I., No. 8, August, 1911).

Charts illustrating the *B. coli* content and the total bacterial count were exhibited. The results obtained varied, but not sufficiently to give positive indications as to results which may be obtained with samples stored at higher degrees of temperature. The variation of individual samples not in storage may, under certain circumstances, be as great as the results obtained on those kept in storage. Additional work on oysters showing greater degrees of pollutions and during different seasons of the year are contemplated before final publication.

Seasonal Variation in the Bacterial Content of Oysters: GEO. H. SMITH.

During the sanitary survey of Narragansett Bay, carried on during 1910-11, several facts were brought out regarding the bacterial content of oysters during different seasons. Frequent examinations of several layings were made during the period from December, 1910, to May, 1911, that is, during the coldest part of the year and during the period of the warming of the water. In these examinations the total count of organisms in the shell-juice of the oyster and the sea-water, the presence or absence of the colon bacillus in the oysters and the sea-water, the temperature of the water, etc., were noted.

An analysis of the data thus obtained seems to warrant the following statements:

During the colder winter months both the total number of organisms and the number of *B. coli* present in the oyster are very low as compared with that of the warmer weather.

The times when the total count and the colon count of the oysters are lowest are not the same, except within wide limits.

The period when the oysters contain the lowest total number of organisms or the fewest *B. coli* is not the period of lowest temperature.

The drop in total bacteria and in colon is apparently not related in any way to the decrease of organisms in the sea-water.

Thus it appears that the decrease in the bac-

terial content of the oyster is not directly dependent upon the number of organisms present in the sea-water, nor is it the direct effect of temperature, but is rather due to some cause lying within the oyster itself. Possibly during the colder months the oyster enters a state of hibernation, when no bacteria are taken in and those already within are gradually eliminated.

Variation in Acid Production of Colon Bacilli from Different Sources: WILLIAM W. BROWN.

During the sanitary survey of Narragansett Bay, Rhode Island, under the direction of Professor Gorham, oysters were taken from 242 stations to determine whether the distance of the oysters from the source of the pollution had any relation to the amount of acid the colon bacillus was able to produce in dextrose and lactose broths, with the hope of determining whether pollution was recent or remote. But the factors governing such an experiment as the tides, currents and winds were so variable that the author could only draw a comparison between the amount of acid produced by colon freshly isolated from feces and the colon isolated from oysters. Oysters were taken from 242 stations in the bay, some located in badly polluted areas, while some were taken from conditional zones (sometimes colon-positive, again colon-negative). In all cases the oysters were examined according to the standard methods of the committee of the Laboratory Section of the American Public Health Association. The fecal colon were isolated from the stools of Italian immigrants. The dextrose and lactose broths used in the experiment were made according to standard methods, except that meat extract was used in all cases.

Titration was made with $N/20$ sodium hydroxide into boiling solutions.

From the titrations it was noted that:

1. The optimum temperature for acid production by the colon bacillus is $37^{\circ}C$.
2. No matter how great the quantity of medium inoculated with the colon bacillus, the same per cent. of acidity is obtained.
3. More acid is produced in dextrose broth than in lactose broth by the colon bacillus.
4. The amount of sugar present in the medium has a direct relation to the amount of acid produced.

5. *Bacillus coli* freshly isolated from feces produces more acid in dextrose and lactose broth than *Bacillus coli* isolated from oysters.

Mutations in Microorganisms: D. H. BERGEY.

The success which seems to have attended the

attempts to produce mutation in some of the animal organisms, especially Trypanosomes, stimulated the hope that it would be possible to produce similar mutations in bacteria. In fact such mutations have been encountered, notably those described by Neisser, Massini and others. I have selected a typical colon bacillus, isolated from feces, as a desirable organism with which to attempt to produce mutation forms. The success which Altmann and his associates had in changing the immunity reactions of the colon bacillus, suggested that it might be possible to change some of its other characteristics. With this object in view, I exposed the colon bacillus to various organic and inorganic substances, added to ordinary bouillon for varying periods of time. I then tested these organisms as to their general biological characters and the immunity reactions. Among the substances to which the culture was exposed were copper sulphate, chloroform, picric acid, resorcinol and horse serum. Thus far none of the biological characters of the organism have been altered—either increased or decreased to any appreciable degree. The immunity reaction, especially the agglutination reaction, appears to show evidences of alteration. These alterations are most marked in the race exposed to horse serum, though all of the chemicals employed seem to so change the organism as to inhibit agglutination altogether or permit its manifestation only in serum of high agglutinative power. The alterations in the characters of the organism are insufficient in degree to warrant one in classifying them as mutations.

The Antiseptic and Bactericidal Properties of Egg-white: LEO F. RETTGER and JOEL A. SPERRY.

Normal egg-white possesses marked antiseptic and bactericidal properties towards certain bacteria, particularly the members of the *subtilis* group. *B. subtilis* and *B. megatherium* were destroyed almost instantaneously when introduced into test tubes containing the whites of hens' eggs. Certain strains of *B. coli* and *B. typhi* were quite susceptible, while others were but slightly affected. The same thing was found to be true of *B. pulchrum* (Rettger). With respect to the last-mentioned organism the degree of resistance bore a definite relationship to the virulence, the more virulent strains showing the greater resistance to the action of the egg-white.

Proteus Zenkeri was quickly destroyed, while *Proteus vulgaris* was less rapidly influenced and *Proteus mirabilis* suffered but little, if any.

Staphylococcus pyogenes aureus and *B. fluorescens* were very quickly affected. *Bacillus putrifiscus* (Bienstock) and *B. edematis maligni* were unable to develop and bring about any putrefactive changes whatever in the white of egg, while the yolk and the coagulated egg-meat medium rapidly underwent putrefaction.

Heating at 65–70° C. for 15 minutes destroys the antiseptic and bactericidal properties of egg-white.

The Effect of Certain Antiseptics upon *Staphylococcus pyogenes* var. *aureus*: T. D. BECKWITH, T. D. BRANDENBERG, J. DINWIDDIE and C. H. HOFSTRAND.

In order to learn the efficiency of certain antiseptics commonly used in veterinary practise the following work was carried out under test-tube conditions.

The antiseptic was added to distilled water with the proper dilution and a loopful of a twenty-four hour culture in broth of *Staphylococcus pyogenes* var. *aureus* isolated about one week previously from a case of empyema was then mixed with the antiseptic solution. Plates were poured, using standard beef agar after intervals of one, five and twenty minutes, all results being obtained in duplicate. The following seventeen compounds and preparations were used: alcohol, pyoktanin blue, pyoktanin yellow, Lugol's solution, potassium permanganate, cresol, liq. cresolis comp., boric acid, lysol, formaldehyde, hydrogen peroxide, silver nitrate, mercuric chloride, phenol, "Benetol," "Creolin," "Septico," the last three being preparations on the market.

Following appeared to be the order of efficiency, beginning with the most active: silver nitrate, mercuric chloride, Lugol's solution, pyoktanin blue, potassium permanganate, pyoktanin yellow, Liq. cresolis comp., cresol, "Benetol," "Creolin," formaldehyde, lysol, "Septico," hydrogen peroxide, phenol, boric acid, alcohol.

Check tubes and counts were made at frequent intervals.

Aggressin Immunisation Against Symptomatic Anthrax: OTTO W. SCHÖBL.

Briefly, the results of the experiments are as follows:

1. The existence of aggressin in black leg edema has been proved, since the sterile edema fluid aids infection by hindering the natural protective apparatus of the organism. Phagocytosis chiefly is inhibited.

2. It is non-toxic even in much larger quantities

than the amount necessary to change a sublethal dose of symptomatic anthrax bacilli into the lethal dose.

3. Repeated injections of sterile edema fluid leads to a considerable degree of immunity. The animals are not only immune themselves, but also yield serum that protects normal animals from subsequent infection.

4. Such a serum shows the presence of antibodies demonstrable both in vitro and in vivo, the most striking characteristic being its favorable effect upon the phenomenon of phagocytosis.

5. In the subcutaneous circumscribed infiltration following artificial infection, immunized animals may under certain circumstances harbor virulent symptomatic anthrax bacilli.

Therefore, the immunity can not be considered bacteriolytic.

6. The immunity consists of a complete or partial inhibition of the growth of symptomatic anthrax bacilli in the body of the immunized animal. If the immunity is not sufficient to suppress completely the growth of bacilli, they multiply locally and are still able to produce toxin. The difference between antitoxic and anti-infectious immunity is in the case of symptomatic anthrax quite evident.

7. The fact frequently observed in our experiments that immune animals may harbor in their bodies symptomatic anthrax bacilli, fully virulent for normal animals, is worthy of consideration from an epidemiological standpoint.

8. The method of immunization with aggressin is advantageous in that the inoculating material is a sterile fluid, hence the danger of making bacillus-carriers or setting up a virulent infection through the vaccinating material is avoided.

The Role of Homologous Cultures in the Production of Immunity in Rabbits to Fowl Cholera:
PHILIP B. HADLEY.

The present paper describes certain aspects of an immunity artificially produced in rabbits against infection with a very virulent culture of the fowl cholera organism. This was accomplished by means of a subcutaneous inoculation with a small amount of a nearly virulent, homologous culture of the cholera bacterium. The following points are made clear:

1. Of ten different strains of the fowl cholera organism employed, only one (Culture 52) was capable of producing immunity to a highly virulent culture.

2. The smallest amount of Culture 52 found to produce immunity was 0.000,000,01 c.c., but

amounts as large as 3 c.c. were easily tolerated and gave similar results.

3. In protectively inoculated rabbits a slight resistance was manifested within 3 to 4 days, but complete immunity did not appear until the seventh day after the protective inoculation.

4. That the resistance in question was not a "zonal" or local immunity was shown by inoculation of previously protected rabbits in the ear, flank and back; also by intravenous and intraperitoneal inoculations, none of which were fatal.

5. The resistance produced by inoculation with 2 c.c. of Culture 52 was sufficient to protect against at least 3 c.c. of the virulent culture when the M.L.D. of the latter was one hundred-quintillionth (0.000,000,000,000,000,001 c.c.) of one cubic centimeter.

6. Both fowls and pigeons have been rendered immune by inoculation with Culture 52. But, whereas a single inoculation is invariably sufficient for rabbits, fowls and pigeons may require two.

7. Attempts to produce resistance by inoculation with killed and attenuated cultures have failed; likewise attempts to produce resistance by successive inoculation with gradually increasing numbers of living organisms; this last is probably due to the fact that inoculation with even 4 organisms is fatal.

8. In rabbits, immunity to the virulent culture has been found to endure for at least 8 months.

9. The immunity obtained through inoculation with Culture 52 is inherited; female rabbits, six and one half months after the protective inoculation, are able to give birth to young which are perfectly immune.

10. The blood serum from resistant rabbits is protective.

Serum Diagnosis of Glanders: JOHN R. MOHLER.

In 1909 Schütz and Schubert published the results of their important work on the application of the method of complement fixation for the diagnosis of glanders. Their experiments were followed by splendid results, exceeding by far those obtained by either the mallein or agglutination test. Consequently, they recommended that this method of diagnosis in combination with the agglutination test be taken as the official test in Germany. This method, overcoming as it does the disadvantages of the mallein and agglutination tests, constitutes the most reliable method for the diagnosis of glanders which we have at our command at the present time. It has recently been thoroughly studied by the Bureau of Animal

Industry and has proved to be highly satisfactory. The principle of this test is presented in the phenomenon of hemolysis, which was first discovered and studied by Bordet and Gengou. This phenomenon consists of the well-known fact that if red blood cells of one animal are introduced into another of a different species, the blood of the latter acquires the power to dissolve the blood cells of the former when mixed with them in a test tube. The substances necessary for hemolysis are, (1) the hemolytic amboceptor, which is the serum of a rabbit that has been injected with washed sheep corpuscles; (2) the complement in the form of normal guinea-pig serum, and (3) washed blood corpuscles of the sheep. In the complement fixation test there are also used, besides the hemolytic system, the serum of the horse to be examined and an extract of glanders bacilli, termed antigen.

The complement fixation test is so called on account of the fact that the complement is fixed by the combination of glanders bacilli extract with antibodies in the serum of a glandered horse, and is thus prevented from participating in the hemolytic process in which it is essential in order for hemolysis to take place. By this method, even small quantities of glanders antibodies (amboceptors) can be demonstrated in a serum.

The complement fixation accordingly represents a specific test, as only in the presence of glanders antibodies and glanders antigen will a reaction take place. The results of the test should be interpreted as follows:

1. Horses in which the serum produces a complete fixation of the complement in quantities of 0.1 c.c. and 0.2 c.c. should be considered as glandered.

2. Horses in which the serum gives a complete fixation in the quantity of 0.2 c.c., and an incomplete fixation in the quantity of 0.1 c.c., should likewise be considered as glandered.

3. Horses in which the serum produces incomplete fixation in quantities of 0.1 c.c. and 0.2 c.c. should also be considered as glandered.

4. Horses in which the serum shows no fixation of the complement should be considered free from glanders.

In order to reduce the possibility of error to a minimum, the agglutination test may be applied to the negative cases, and if this shows a value of 1:1,000 or over the animal should be considered as glandered. However, such cases are extremely rare.

The Effects of Subdural Injections of Leucocytes on the Development and Course of Experimental Tuberculous Meningitis: WILFRED H. MAN-
WARING.

The injection of suspensions of tubercle bacilli into the basal meninges of dogs causes a tuberculous meningitis, characterized by a latent or incubation period of from five to thirty days, depending on the dosage and virulence of the culture injected, followed by a period of increasing paralysis and incoordination, ending almost invariably in death.

The injection of homologous leucocytes into the basal meninges of these animals, during the latent or incubation period of the disease, has the uniform effect of delaying the development of the paralytic symptoms. In dogs injected with small doses of tubercle bacilli of low virulence, the development of the paralytic symptoms has been prevented by this means for a period of seven months (up to the present time), while the untreated control animals, injected with the same doses, have all developed paralyses within a period of about four weeks, from which half of the untreated dogs have thus far died.

In press, *Journal of Experimental Medicine*, 1912.

Simple Methods in the Bacteriological Diagnosis of Cholera: CHARLES KRUMWIEDE.

Two points were kept in view, viz., the possibility of examining enormous numbers of cases with the minimum of equipment and the rapid preparation of media for immediate use in emergency.

In general, no medium is necessary but peptone water. If the feces contain a sufficient number of cholera vibrios, the peptone cultures after eight to twelve hours have practically a pure culture at their surface. If a drop of this and immune serum be mixed, the microscopic agglutination is so prompt and evident as to be diagnostic.

In examining carriers or mild cases the first peptone tubes may show little or nothing. If, however, some of the surface growth be subinoculated in a second series of peptone tubes and incubated, the surface growth becomes sufficiently pure for testing the agglutinability of the vibrios.

In four instances we have been unable to make a diagnosis till the end of the second enrichment.

Vibrios other than cholera can be excluded by their inability to enrich or by the absence of any influence of the agglutinating serum. Where they are few in number, as for instance in the first

enrichment, a tentative diagnosis can be made by the influence of the serum on their motility. The motility of cholera and the very closely allied vibrios is so marked as to be evident even in mixed cultures.

We were able by this method to diagnose two carriers among the passengers of one ship, 50 per cent. of whom had cholera-like vibrios in their stools. The results were all verified by the use of the Dieudonne medium.

A Simple Selective Medium.—We have tried to avoid the use of defibrinated blood, which is not always obtainable in emergency. The following formula, substituting eggs, gives equally favorable results:

- | | |
|--|-------------------------------|
| A. Whole egg and water a.a. | } Mix in equal |
| Sodium carbonate (crystalline,
12 to 13½ per cent.) | |
| B. Meat free agar, viz., peptone, salt and 3 per cent. agar. | } parts, steam
for 20 min. |

Mix A, 30 parts, and B, 70 parts, while the agar is boiling hot. Pour medium to thick plates, allow them to stand open for 20 minutes to dry and then inoculate by surface streaking.

Should other fecal bacteria grow, the cholera colonies can easily be selected. The latter have a distinctive hazy outline and appear to be deep in the agar. With longer incubation a zone of clearing appears about the colonies.

Studies on Etiology of Equine Influenza: N. S. FERRY.

A Streptococcus, presumably the organism described by Schültz and others, has been cultivated uncontaminated from the trachea in the early stages of nearly every case of acute influenza studied.

An organism with the same characteristics has been isolated from the blood of thirty-four out of sixty-three cases.

Symbiotic relationship with the Staphylococcus, in broth cultures, seems to favor the growth of this Streptococcus.

This organism was able to pass many times through Berkefeld filters, and a few times through Chamberland filters, showing that it is a very minute organism in some stage of its life cycle.

The *Bacillus equisepticus* has not been seen in, nor isolated from, either the trachea or blood of a single case of influenza, therefore, Lingnieres's findings have not been corroborated.

We have not been able to find any points of difference between this organism and the Strepto-

coccus isolated from the abscesses in the cases of strangles.

Inoculation experiments were not extensive enough to warrant any conclusions as to the infectious nature of the organisms. We have record, however, of one case with the fever, prostration, cough and discharge from the nostrils, which was very characteristic of influenza. This followed the intravenous injection of a pure culture of the organism. We had another case of a large tumor at the site of inoculation after a subcutaneous injection of the same culture.

From the light of our work, up to the present time, we do not feel justified in stating positively that this *Streptococcus* is the cause of influenza in horses, but we do believe that the findings point very strongly to that conclusion.

If this proves to be the same organism that is found in strangles and also contagious pneumonia, and it is agreed by all authorities that the *Streptococcus* found in strangles is the cause of that disease, then, we believe, we are justified in putting forward the argument that this *Streptococcus* is the cause of the symptom complex we have termed "influenza," and that strangles and contagious pneumonia are not clinical entities, but complications of influenza due either to secondary infections or to extension of the primary disease.

The Influence of the Carrier in the Management of Institutional Diphtheria: J. J. KINYOUN.

The writer reports that since 1908 it has been the custom of the Health Department when a clinical case of diphtheria is reported from any institution to make an examination of all the contacts. Since beginning this there have been reported 23 clinical cases of diphtheria from 14 institutions. Cultures taken from all the contacts, immediate or remote, gave 220 carriers out of 2,004 contacts. In all the institutions save one there were no further cases. In one over which the Health Department acted only in an advisory capacity, and where there was not a complete culturing of all the contacts, other clinical cases did occur. Such cases did not cease until all the contacts were cultured. All bacillus carriers are considered as if they were clinical cases and are subjected to the same quarantine methods.

The writer finds that there is no arbitrary rule for the discharge of the carrier from quarantine, but must be done on the culture test. An analysis of the 199 cases of the carrier shows that the first negative culture from these was as follows: 20 cases on the 3d day; 18 on the 4th day; 30 on the

5th day; 34 on the 6th day; 30 on the 7th day; 22 on the 8th day; 10 on the 9th day; 2 on the 10th day; 5 on the 11th day; 10 on the 12th day; 9 on the 13th day; 3 on the 14th day; 3 on the 16th day; 2 on the 18th day; 1 on the 30th day. In none of these carrier cases were there any clinical symptoms.

The writer agrees with McDonald that the control of diphtheria is the control of the carrier.

A Panum Incubator with Important Modifications: LEO F. RETTGER.

In the construction of an incubator designed to meet the general needs of a bacteriological laboratory, the Panum model as described in Klöcker's "Fermentation Organisms" was chosen. The construction work was entrusted to a skilled copper-smith in New Haven. Copper was used throughout, except in the hinges of the doors, which are of brass, and the outer wall of the incubator, which was made of one-inch wood. Three inches of felt were packed between the outer and inner walls. Instead of being provided with four large outer doors which are fastened by hinges on the floor of the incubator, the incubator has eight doors, two for each main, square, compartment. The doors are in pairs, they swing on hinges and close in such a way that one door fits closely against the other. The doors are about three inches thick, and at the same time light in weight, as the space within the two walls is filled with air. Each of the eight compartments, excluding the refrigerator, is further provided with a glass door, which is easily removed. A gas safety lamp is the source of heat for the blood temperature end of the incubator. The compartment which is heated directly by the flame is surrounded completely with water. The water jacket is connected with a small water container which is made of copper. As the gas pressure is fairly uniform, this arrangement has given entire satisfaction. A Reichert thermo-regulator is installed.

When the refrigerator end is kept well supplied with ice the incubator is remarkably efficient. The temperatures in the different compartments are practically constant. This has been demonstrated particularly in a long series of experiments in which frequent and painstaking determinations were made.

All abstracts have been supplied by authors unless otherwise stated.

INTRODUCTION

NOTWITHSTANDING the great area of Alaska, the ruggedness and inaccessibility of a large part of the glaciated region, and the briefness of the period of exploration, we are already in possession of a large body of fact with regard to the glaciers and glaciation of our northern territory. The researches of Wright,² Russell,³ Reid,⁴ Gilbert,⁵ Davidson,⁶ Dall⁷ and others have given us much valuable information concerning the coastal region; and the many expeditions by Hayes,⁸ Brooks, and various other members of the United States Geological Survey⁹ have added ma-

terially to this knowledge, and have extended the area of observation to the interior. Thus, even though there is yet much to learn, the knowledge that we now possess is sufficient to warrant a discussion of the general phenomena of Alaskan glaciation; and since this is the object that has been most in my mind during the past six years, it has naturally appealed to me as the most fitting topic for the presidential address which I am called upon to give.¹⁰

THE EXISTING GLACIERS

Condition of the Existing Glaciers

Alaskan glaciation is, and has been, of the mountain type. That is to say, mountain snow fields have shed into mountain valleys, and through these the glacier ice has flowed to lower levels, in some cases even to the sea. Numerous glaciers, and in former times a still greater number, have flowed beyond their valleys and spread out fan-shaped at the mountain base, giving rise to the type of *piedmont* glacier which Russell has made known to us through his studies of the Malaspina glacier.

The main region of existing glaciers occupies a roughly semicircular area sweeping from the southern boundary of Alaska, northward, westward and southwestward,

¹⁰ The personal field work upon which this address is in part based was done in 1905 and 1906 under the auspices of the U. S. Geological Society; and in 1909 and 1911 under the auspices of the Research Committee of the National Geographic Society. To both of these bodies acknowledgments are due for the generous financial support given. The last two expeditions have been under the joint leadership of Professor Lawrence Martin and myself; and I wish especially to acknowledge my indebtedness to my colleague in two seasons of work, who was also an assistant on the first expedition. We have worked and observed together and have freely discussed all problems which have arisen. The results of our joint work are used in this address, as are also the results of other students of Alaskan glaciation.

toward the Aleutian islands. From either end of this zone both the number and the size of the glaciers increase, and the elevation of their termini decreases, attaining maximum development near the center of the semicircle that surrounds the head of the Gulf of Alaska. Altogether there are at least 47 tidal glaciers in this zone, the southeasternmost being the Le Conte Glacier, just north of Wrangell, and the westernmost McCarty Glacier on Kenai peninsula. Toward the ends of the glacier zone there are few and scattered instances of tidal glaciers; but in the central part of the zone they are numerous, and, where topographic conditions favor, are close together. Thus in Glacier Bay there are at least twelve tidal glaciers; in Yakutat Bay three; and in Prince William Sound twenty.

How many glaciers there are in this coastal area can not be even approximately estimated; but, counting large and small, tributaries and main ice streams, they are certainly to be numbered by the thousand. These vary in size from tiny ice masses in cirques, to valley glaciers two or three miles in breadth and thirty or forty miles in length; and up to the great Malaspina Glacier whose area is estimated to be 1,500 square miles. From the Kenai peninsula to Cross Sound a very large proportion of the seaward face of the mountains is covered with snow and ice, and glaciers exist in a majority of the valleys, deeply filling most of the larger ones. From Controller Bay to Cross Sound a succession of piedmont glaciers and expanded bulbs of individual glaciers spread out between the mountain base and the sea. A journey along this coast is, therefore, a constant glacial panorama.

Distribution of Existing Glaciers

The mountains which fringe the Alaskan coast as a continuous barrier, as far west

as Cook Inlet, attain their greatest elevation in the St. Elias-Fairweather Range where peaks rise 12,000 to 15,000 feet, 18,000 feet in Mount St. Elias, and 19,540 feet in Mount Logan. Here, naturally, the glaciers are largest, for from this central area the general elevation, as well as the heights of the peaks, diminishes toward both the southeast and the west.

Back from the coast, and roughly parallel to the curving mountain barrier around the head of the Gulf of Alaska, is another lofty range sweeping northward from the Alaska peninsula, then eastward and southeastward. In its highest part, called the Alaska Range, are numerous lofty mountain peaks, including Mount McKinley (20,300 feet), the highest mountain in North America. Between this interior range and the coastal mountains is a broad depression occupied by Cook Inlet in the south and the Copper River Basin in the east; but in the extreme east the area between the two mountain ranges is mainly occupied by the great volcanic group known as the Wrangell mountains, whose peaks attain elevations of from 14,000 to 16,000 feet.

Naturally these lofty mountains of the interior are also the seat of numerous and large glaciers. But neither here, nor on the inner face of the coastal mountains, is there so full a development of ice and snow as along the coast. The snow line is higher, the glacier ends are all necessarily well above sea level, and the piedmont type of glacier is absent. The glaciers are essentially confined to the mountain valleys, though some extend to the mouths of the valleys, and a few spread slightly beyond them. It must not be inferred that the glaciers of the interior are insignificant either in size or in number; merely that they suffer in comparison with their larger neighbors nearer the sea. Were

they the only glaciers of Alaska they would themselves attract wide attention because of their number and size. Besides being dwarfed by comparison with the coastal glaciers, these in the interior have the disadvantage of remoteness and relative inaccessibility. They are, therefore, far less well known than the glaciers of the coast.

The difference between the glaciers on the two sides of the coastal mountains may be typically illustrated by the Valdez-Klutena system, two glaciers which descend in opposite directions from a common divide in the Chugach mountains, at an elevation of 4,800 feet. The Valdez Glacier, descending on the seaward side of the mountains, is 19 miles long and ends at an elevation of 210 feet, while the Klutena Glacier, descending toward the interior, is only 6 miles long and ends at an elevation of 2,000 feet. A similar difference is observed in the Nizina and Chisana glaciers, which descend from a common divide at an elevation of 8,000 feet in the Wrangell Mountains, the former descending on the side facing the sea and therefore being much longer than the Chisana Glacier, which flows toward the interior. The total length of the two ice streams is about 47 miles.

Beyond the Alaska Range, although there are numerous mountain and plateau areas of considerable elevation, lying far to the north, there is a general absence of existing glaciers, the only exception, so far as known, being on the Arctic slope of the Endicott Mountains (5,000-8,000 feet). Here, in the summer of 1911, Phillip S. Smith and A. C. Maddren¹¹ observed a number of small valley glaciers.

Explanation of the Distribution of the Glaciers

The distribution of glaciers in Alaska is not difficult to explain. That they are so

¹¹ Personal communications to the author.

extensively developed along the seaward face of the coastal ranges is plainly due to the fact that the prevailing winds are from the ocean, and that in blowing over the warmed waters of the Gulf of Alaska a large amount of vapor is moved forward and precipitated in the form of snow upon the lofty mountain barrier. It is where the coastal barrier is most complete and highest that the snowfall is heaviest and the development of glaciers greatest. The annual precipitation varies greatly, records of from 100 to 190 inches having been obtained at stations along this coast; but there is no knowledge as to the precipitation among the lofty mountains, excepting the knowledge that it is very heavy and mainly in the form of snow.

In a region where from 10 to 40 feet of snow falls each year at sea level, there must be exceedingly heavy snowfall at elevations where the precipitation is all in the form of snow. As an indication of the vast snowfall among the mountains, reference may be made to Schrader's observation of from 8 to 12 feet of snowfall on Valdez Glacier during a week late in April and early in May, 1898. By such heavy precipitation the snowline is depressed to levels of 2,500 to 3,500 feet on the seaward face of the mountains, and to even lower levels back in the mountains where the local climate is cooled by the chill of the surrounding areas of snow and ice.

Since the damp winds precipitate so much vapor in crossing the mountain barrier, there is a deficiency for precipitation on the inner slopes of the mountains and on the ranges further inland. Moreover, such winds as sweep into interior Alaska from either the Arctic Ocean or Bering Sea bear but a limited vapor burden, since the water of these seas is cold in summer and more or less completely ice-covered in winter. Records at Eagle give a rainfall of only

11.35 inches; but the precipitation is doubtless higher toward the west and in the lofty mountains.

The winters of the interior are prevailingly clear and cold with moderate snowfall—for example, only 2 or 3 feet of snow falls in the Copper River Basin; but in spring and summer the temperature is so high that the snow quickly melts even well up on the mountain slopes. Thus, even in the neighborhood of the Arctic Circle a plateau from 3,000 to 6,000 feet in elevation is completely free from snow in summer, as is also a large portion of the Endicott mountains; and, whereas the snowline on the seaward face of the St. Elias range is about 3,000 feet, it is more than twice as high as that in the interior three or four hundred miles further north. The exact elevation of the snowline in the interior can not be stated, and indeed it must vary greatly from place to place. In general, however, it is above 6,000 feet.¹²

This rise in the snowline toward the north is interesting as showing how important the element of precipitation is. The snowline is lower and the glaciers are larger where the mean annual temperature is high and the precipitation is heavy, than in the much colder climate further north where, however, precipitation is light and the short summers are warm. A similar variation is noticed in the coastal mountains where the snowline is considerably higher along the inner fiords than on the outer coast where the precipitation is heavier. It is to be noted, however, that in the latter place not only is there a greater depth of snow to be melted, but in the neighboring lofty mountains there are

¹² Oscar Rohn (Twenty-first Annual Report U. S. Geological Survey, pt. 2, 1899-1900, p. 413) states that on September 1 the snowline was 7,500 feet in one part of the Wrangell Mountains, and was then descending.

broad expanses of snow and ice which serve to retard summer melting.

In the distribution of its glaciers Alaska presents a striking contrast to that part of Europe in the same latitude. There are no glaciers in southern Scandinavia, in the latitude where, in Alaska, the glaciers are largest; and while in Norway there is an increase in glaciation northward, in Alaska there is a decrease. In Norway the influence of latitude is permitted to exert its normal effect; but in Alaska the influence of latitude is effectually counterbalanced by variations in topography and in the vapor content of the air. This contrast may have some significance in the explanation of the development of extensive ice sheets in northwestern Europe and northeastern America, while northern Asia and northwestern North America, in the same latitude, were free from continental glaciation.

Ice Flooded Valleys and Through Glacier Systems

Only by individual description of a large series of instances would it be possible to adequately portray the varied characteristics of the Alaskan glaciers. As in the Alps, Caucasus and Himalayas, the valley glacier is the normal type, but with many variations in form, size and rate of motion. From the lofty peaks a series of radiating glaciers usually spread outward; but throughout much of the mountain area there is a complex of ramifying glacier systems. Nowhere, so far as known, is there a development of the ice cap condition such as is found in Norway, Spitzbergen and Iceland, for the mountains are so lofty and rugged that the valley slopes serve to drain away the surplus snow that falls upon the steep mountainsides.

Still the snowfall is so heavy, especially near the coast, that, in the process of

drainage, the valley systems are deeply filled with ice in spite of the ruggedness and high elevation. In the area of greatest glacier development, in the St. Elias region, the extent of snow and ice is so great as to have led Russell to speak of it as "a vast snow-covered region, limitless in expanse, through which hundreds and perhaps thousands of barren, angular mountain peaks projected," and to compare it to the "borders of the great Greenland ice sheet." How deeply these vast glacier systems fill the valleys we have no means of telling; nor can we even estimate the aggregate length or area of the maze of ice streams that flood the mountain valleys. In a region where dozens of glaciers are known to have lengths of from twenty-five to forty miles, it can not be doubted that the aggregate length of the ice streams is thousands of miles, and that the total area of snow and ice amounts to tens of thousands of square miles.

Although the vast bulk of ice that is slowly draining away the snow that falls among the Alaskan mountains maintains the valley glacier condition rather than developing an ice cap, it gives rise to an intermediate condition, as Russell's description intimates. That is, although the mountain summits are not flooded, the valleys are. For example, one may start from Yakutat Bay and, traveling up one of the large glaciers, rise above the snowline by a moderate grade and finally reach a flat, snow-covered divide, beyond which, also with moderate grade, a descent leads down a glacier flowing in the opposite direction. Or, to the right or the left, also over flat, snow-covered divides, an easy route is open down other glaciers. In this way one may travel for scores of miles, going from one valley to another and from one glacier to another, but crossing only broad, flat snow divides. So deeply is the region submerged

by ice that both the valley bottom topography and the valley head divides are so smoothed out as to give rise to a continuous, connected glacier system with drainage in different directions from flatish divides; but both the divides and the glacier distributaries from them are walled in by steeply rising mountains, each portion of the system having the characteristics of the valley glacier. For such a complex I have proposed the name—*through glacier system*.

The through glacier condition is rendered possible by presence of low divides, and it is believed that, in general, these have originated during an earlier period of more intense glaciation when the snow and ice accumulated to much greater depths than now and flowed across the divides, lowering them by glacial erosion.

In its main essential characteristics, even the through glacier system belongs in the class of valley glaciers; and the valley glacier phenomena in Alaska are in the main the same as those with which we are already thoroughly familiar from the studies of glaciers in the Alps, Himalayas and other mountain regions. As compared with those of the Alps, the larger valley glaciers of Alaska are far greater, and this naturally introduces corresponding differences in form and behavior; but these are differences in detail rather than in underlying principles, and may therefore be dismissed in the present discussion.

At their termini some of the Alaskan glaciers present features not found in the Alps, notably the termination in tidal cliffs from which icebergs are discharged, and expansion on the land to form piedmont bulbs and piedmont glaciers. At a period of former expansion of glaciers, the piedmont condition was present in the Alps also; and the present Alaskan glaciers are more comparable with those expanded

Alpine glaciers than with their shrunken descendants of to-day.

Development of the Cascading Glacier

As in other mountain regions, the present-day Alaskan glaciers, though very large, are mere remnants of a former far greater system, occupying the lower levels of valleys which were profoundly deepened by erosion when the former greater ice masses occupied them. Accordingly, the surface of the present-day glaciers, in the main valleys, is very often well below the level of the surface of the tributaries, which therefore descend with steep slope at their lower ends. There is every gradation, from the accordant junction of tributary and main glaciers, to the ice step, or "bench," where the two join; to the cascading descent of the tributary as it joins the main ice stream; and to the former tributary, now cut off from junction with the main glacier, but cascading toward it in its lower portion where it passes out of its hanging valley and descends the steepened valley slopes in a series of broken steps like a great frozen waterfall. This condition is so well developed in Alaska, and is so widespread and so characteristic, both in form and cause, that the descriptive name *cascading glacier* has been proposed for it.

Development of the Ablation Moraine

Glacial erosion, which has produced extraordinary topographic change in the Alaskan mountains, has, among other results, given rise to very steep valley walls. Such steep slopes, produced by ice erosion during the higher stage of the glaciers, are now, on exposure to the air, in a state of instability under the attacks of the agents of subaerial denudation. Therefore, they weather rapidly, and from them rock falls and avalanches frequently descend. This

rock, mixed in the snow out of which the glacier is made, and spread out over its surface, is concentrated by ablation in the dissipator until the ice surface often becomes completely covered by a sheet of moraine, to which the name *ablation moraine* has been given. It is naturally upon the lower ends of the glaciers that the ablation moraine is most extensively developed; but in some instances it extends far up the valleys, almost or quite to the snow-line. Then the valley glacier looks so little like an ice stream that it may not be recognized as one by the casual observer; and on some of the Alaskan maps such glaciers have found no place.

Since only a portion of the Alaskan glaciers bear ablation moraine it is evident that special conditions are demanded for its development. It is best developed on those ice tongues with steep walls and steep heads, whose width is not too great for avalanches to spread out well toward the middle, and whose valley walls are of a friable rock. In proportion as these conditions vary, the extent of the moraine sheet also varies. Normal weathering and the spread of the falling rock through the snow fields and over the ice tongues are undoubtedly sufficient to account for the formation of a sheet of ablation moraine; but the excessive development of such moraine in some portions of the Alaskan region may perhaps be due in part to the aid which earthquake shaking gives in the downthrow of avalanches from the glacier valley walls. When a glacier bearing a sheet of ablation moraine has melted away, it leaves not only a deposit of till with scratched stones, but overlying this a sheet of coarse, angular fragments and weathered materials. Such deposits are to be expected in mountain regions of former glaciation.

Influences Modifying Rate of Recession of Glaciers

The ablation moraine is one of the factors influencing the position and rate of recession of glacier fronts; another factor is the position of the front, whether on the land or in the sea; for in the latter case recession is far more rapid and active than in glaciers ending on the land. For example, in the St. Elias region, while the Guyot, Seward, Marvin, Lucia, Yakutat and other glaciers that end on the land have spread out from one to twenty miles beyond the mountain front, the great, rapidly-moving tidal Hubbard Glacier, near by, ends at the head of Disenchantment Bay, ten miles or more back among the mountains. Both tidal and non-tidal glaciers are exposed to surface wastage by melting and evaporation; but the tidal glaciers are further exposed to the effective attack of the salt water which quickly removes the ice fragments that fall into it. Therefore, other things being equal, the tidal glacier will naturally terminate farther back among the mountains than non-tidal glaciers of similar character.

Glaciers advancing into rivers are also actively attacked, as is illustrated by the Childs and Miles glaciers in the Copper River Valley, and by glaciers in the Alsek Valley. To a lesser degree the same tendency to more rapid retreat is present in glaciers that terminate in lakes, as the Yakutat Glacier does.

Among ice tongues ending on the land there is great difference in the rate of wastage according to exposure and elevation; but even more important is the protective influence of the cover of ablation moraine. This finds best illustration in those glaciers which spread out fan-shaped at the mountain base, attaining a state of stagnation or semi-stagnation along their margins. Here, near sea level, in a rainy,

temperate climate, wastage by ablation would normally be active, and if the ice supply failed the glaciers would rapidly recede. But the sheet of ablation moraine that develops serves as a blanket against both melting and evaporation, and the rate of wastage so decreases with increase in thickness of the morainic cover that there finally comes a condition of almost complete protection. When the moraine cover is no longer subject to frequent undermining and slumping, vegetation finds a foothold, and ultimately even a mature forest may spread over the moraine that blankets the ice. Glacier recession under such conditions almost ceases and an ice terminus may remain for scores of years without notable change, even though ice supply is completely cut off.

In view of the fact that a protected ice terminus may remain so long in one position, it follows that the piedmont condition is not necessarily proof either of recent expansion or of a continuance of ice supply after expansion. Indeed, there is reason to believe that the piedmont glaciers, and the piedmont bulbs of individual glaciers in Alaska have been formed by expansion at entirely different periods. In some the supply is still being maintained and the ice terminus is kept in place by the essential balance between supply and wastage. This seems clearly to be the case in the greater part of the Malaspina Glacier; but elsewhere there is evidence that the expansion occurred during an earlier period of advance, and that the ice supply has long since been withheld. This is true of the piedmont bulbs of Galiano and Lucia glaciers, to the ends of which the effects of even a recent notable advance did not extend. In still other cases, the ends of the bulbs have become almost or even completely separated from the main glacier by wastage of clear ice

areas back of the terminus. The piedmont bulb develops during a period of advance; it may linger, in more or less mutilated condition, through a period of stagnation, receiving redevelopment when next an advance of sufficient volume occurs. In other words, it does not necessarily represent an existing state of activity and supply; for, because of the protection of a blanket of ablation moraine, it may long retain its position even in the face of warmth, abundant rainfall and failure of ice supply.

Marginal and Terminal Deposits

Since on the seaward side of the coastal mountains, the ends of so many large glaciers lie in a temperate, rainy climate, the phenomena of terminal and marginal deposit are illustrated with great clearness, throwing much light on the origin of similar phenomena in the deposits of former continental glaciers. Particularly is this true of the piedmont areas, not only because of the wide extent of their margins, but also because they are existing examples of a type of glacier that was formerly common in the mountain regions of both Europe and America. It can not be made a part of this address to consider this subject in detail, interesting and important thought it is.¹³ Suffice it to say that in Alaska one may see in process of development both lateral and terminal moraines in great variety of form and composition, from stratified gravel or sand, or clay, to true till; eskers and kames; outwash gravel plains and kettles of various forms and sizes; lacustrine deposits of many kinds and marginal lakes of various origins; marginal channels due to erosion

¹³ See Tarr, R. S., "Some Phenomena of the Glacier Margins in the Yakutat Bay Region, Alaska," *Zeitschr. für Gletscherkunde*, Vol. 3, 1908, pp. 81-110; also, "The Yakutat Bay Region, Alaska," U. S. Geol. Survey, Professional Paper 64, 1909.

and the work of marginal streams in deposit; indeed almost the whole series of phenomena which were present along the receding margins of the Pleistocene glaciers. There are phenomena of recession, of advance, and of alternate recession and advance in the course of which soil beds and plant remains were incorporated between distinct sheets of glacial deposits.

Of all the deposits at present being made in association with Alaskan glaciers, those made by the glacial streams are by far the most prominent. During the summer, torrents of water issue from the margins of the glaciers, and, where the ice is stagnant or thin enough for the existence of subglacial tunnels, from the central portions also. These torrents, doubtless esker-building beneath the glacier, spread out over alluvial fans, or broad outwash gravel plains, or long, narrow valley trains, which they are upbuilding by the extensive deposition that is made necessary by the overburdened condition of the streams on their escape from the ice tunnels. Over such a deposit the streams spread in a multitude of anastomosing branches, ever shifting in position as they aggrade their beds in the effort to establish a grade sufficient for the transportation of the sediment load. Within a few miles of the glacier front the slope of the aggrading streams may average 50 or 60 feet to the mile, and close by the glacier even much more than this.

So great is the velocity of the glacial torrents that good-sized stones are dragged along, and one can hear them striking together as they roll on down stream. First the boulders are dropped, then the gravel, then the sand, and with the change in material deposited is an associated change in grade; but throughout their course the grade of the glacial streams is commonly very steep, for they are normally so charged

with sediment, and much of the sediment is so coarse, that it quickly settles in a slow current. Schrader says that in its upper course the Klutena River has a grade of 60 feet a mile, then for 28 miles an average grade of 22 feet a mile and a velocity of 14 miles an hour. The Copper River, into which it empties, flows with a velocity of 8 miles an hour.

The Sediment Supply of the Glacial Streams

In volume, slope and sediment load the Alaskan glacier streams are noteworthy. During a period of a few months each year the drainage of a wide area, locked up in the form of snow and ice, is turned into torrents of running water which issue as full-fledged streams, and even as veritable rivers from near the glacier ends. A glacier that is just at the balance between supply and melting furnishes to the streams only that water which is brought down to or near to the ice front; but in a glacier that is receding, there is added to this supply all that which is melted from the ice that is no longer moving forward. Therefore, where, as is so often the case in Alaska, the glaciers are stagnant or receding, the supply of water exceeds the normal.

The impressive volume of sediment, fine and coarse, which the glacial streams are transporting leads the inquiring mind to raise the question as to its origin. Streams having their source in the rainfall are not often so sediment-laden as the glacial streams normally are; indeed, even the exceptional land-supplied streams are rarely as heavily burdened, even for a few days, as the glacial torrents normally are for several months. Particularly is the question of the origin of the finer grained sediment of interest. It is abnormal in quantity as compared with mountain streams in gen-

eral, and yet it comes from a drainage area largely protected by snow and ice against those atmospheric agencies which transform hard rock to fine clay. Can there be any doubt but that the glacier which protects the rock against the atmospheric agencies must attack it with equal or even greater vigor, in order to obtain this vast burden of sediment that the streams bear away?¹⁴

The Recession of Glaciers in Alaska

Throughout the world the general state of the glaciers is one of recession, with local exceptions; and it is as true of Alaska as of other regions. In the two regions where we have the longest record and the most detailed studies—Glacier Bay and Yakutat Bay—there have been great recessions during the period of observation, the continuation of a still greater earlier recession during the last century or more. For instance, in Yakutat Bay the tidal Nunatak Glacier receded at the rate of over 1,000 feet a year between 1899 and 1906, with a total recession of over a mile; and the nearby Hidden Glacier, ending on the land, receded at about a quarter of this rate. Prior to this observed recession, both Hidden and Nunatak glaciers had been so far advanced that they united and their combined front reached about 20 miles farther out than the present end of Nunatak Glacier, and 10 miles beyond the present terminus of Hidden Glacier. From this advanced position there has been rapid and long-continued recession which was in progress up to 1906 in Hidden Glacier, and up to 1909 in Nunatak Glacier. If the observed rate of recent recession of Nunatak Glacier has been steadily maintained throughout the period, it is to be reckoned as of about a century duration.

¹⁴ See von Engeln, O. D., *Zeitschrift für Gletscherkunde*, Band VI., 1911, pp. 138-144.

In Glacier Bay the phenomena have been closely like those of Yakutat Bay. A long-continued recession had been in progress when the Muir Glacier was studied by Wright in 1886, and by Reid in 1891 and 1892, when Muir Glacier front was about 20 miles further inland than it had been 100 or 150 years before; and Grand Pacific Glacier front was about twice that distance back of the former terminus. Where ice had formerly filled the mountain-walled valley to a depth of 3,000 feet, the flood waters extended in 1892. This recession has continued since then, being especially noteworthy since 1899; and now (1911) both the Grand Pacific and the Muir Glacier fronts are 9 or 10 miles farther back than in 1892, the average recession being at a rate of not far from 2,500 feet a year for the 19 years; but it is to be noted that the rate has not been regular, and that the greater part of the recession has occurred since 1899. The retreat has continued up to 1911 in all the glaciers of Glacier Bay with the single exception of Rendu Glacier (and a small cascading glacier near it), which has recently advanced about a mile and a half. Glacier Bay has been enlarged no less than 50 square miles by ice recession in a period of 19 years. Assuming an average thickness of 750 to 1,000 feet, the total loss of ice in this period is not less than 6 or 8 cubic miles. But to this must be added that which has been lost by ablation from above the present ice surface; and this is also an enormous amount, for all the outer glacier surfaces, even far back from their fronts, are now much lower than they were in 1892.

While these instances are the most striking of which there are records in Alaska, in our own studies Professor Martin and I have observed scores of other cases, widely separated, where there has been notable recent recession and where it is still in prog-

ress; and many instances have been made known to us by the observations of other workers. Therefore, the commonly accepted conclusion that recession is the general rule among the Alaskan glaciers is fully warranted; yet the rule is by no means invariable. For example, Columbia Glacier began advancing in 1908, and Professor Martin found it still advancing in 1910, while in the same year he observed commencement of advance of several glaciers of different sizes in Prince William Sound and Copper River valley. We know also of recent advance of other Alaskan glaciers, the total known to us to have advanced since 1899 being 43, nine of which are in Yakutat Bay; but some of these 43 advances are exceedingly slight; and 43 glaciers form but a minute proportion of the whole number of Alaskan glaciers. These facts demonstrate that it can not be assumed either that the recession is universal, or that it is not liable to interruption. Too little is known about Alaskan glacier history and about Alaskan climate and its variations to warrant any generalization with regard to the possible future of its glaciers; it is not even certain that the present state of general recession is anything more than an episode.

Advance of Glaciers as a Result of Earthquake Shaking

Of all the recent glacier advances of which we have record in Alaska, by far the most interesting are those of Yakutat Bay. Following the vigorous earthquakes of September, 1899, and, as I have elsewhere endeavored to show,¹⁵ as an indirect result

"I have presented this theory in various publications, and in these have given a full statement of the facts and a discussion of their bearing on the theory; so that, in view of the character of this address and its necessary brevity, only a very short and general statement is attempted. See especially Tarr, R. S., "Second Expedition

of them has come a series of forward movements and transformations of a very spectacular character, interrupting a period of general recession and affecting even stagnant glaciers and piedmont bulbs. First there came a spasmodic advance of at least two small glaciers, and probably others that we failed to detect on our first expedition in 1905; then, in the interval between September, 1905, and June, 1906, an advance occurred in four larger glaciers; in 1906 and 1907 the Hidden Glacier advanced; in 1909 the still larger Lucia Glacier; and in 1909-10 the Nunatak Glacier advanced. The progressive appearance of the advance, correlated with the length of the glaciers, has been set forth in the following table prepared by Professor Martin:

Name of Glacier	Date of Advance	Approximate Length of Glacier
Galiano	After 1895 and before 1905	2 or 3 miles
Unnamed Glacier	1901	3 or 4 miles
Haenke	1905-6	6 or 7 miles
Atrevida	1905-6	8 miles
Variegated	1905-6	10 miles
Marvine	1905-6	10 miles (exclusive of portion in Malaspina piedmont area)
Hidden	1906 or 1907	16 or 17 miles
Lucia	1909	17 or 18 miles
Nunatak	1910	20 miles

The advance involved a profound breaking of the glacier surface even where pre- to Yakutat Bay, Alaska," *Bull. Geog. Soc. Philadelphia*, Vol. 5, 1907, pp. 1-14; "Recent Advance of Glaciers in the Yakutat Bay Region, Alaska," *Bull. Geol. Soc. America*, Vol. 18, 1907, pp. 257-286; "The Yakutat Bay Region, Alaska," Professional Paper No. 64, U. S. Geol. Survey, 1909; "The Theory of Advance of Glaciers in Response to Earthquake Shaking," *Zeitschrift für Gletscherkunde*, Vol. 5, 1910, pp. 1-35; also Tarr, R. S., and Martin, Lawrence, "Recent Changes of Level in the Yakutat Bay Region, Alaska," *Bull. Geol. Soc. America*, Vol. 17, 1906, pp. 29-64; "The Yakutat Bay Earthquakes of September, 1899," Professional Paper No. 69, U. S. Geol. Survey, 1912 (in press).

viously smooth and uncrevassed; the lower portion of the glacier was greatly thickened; where unconfined between mountain walls there was a notable spreading at the margins; and the free ends of the glaciers were bodily moved forward. In all cases the transformation was rapid and even spasmodic, requiring a period of but a few months for the complete cycle; and in all cases the advance was quickly followed by relapse into the previous state. In other words, a wave spread down through the glaciers with accompanying thickening, spreading, advance and breaking of the rigid upper ice; but after passage the glacier was left in essentially the same state of activity as before, even though that state had been complete stagnation in parts of the affected area.

In some cases the wave spent its effects in breaking, thickening and spreading a piedmont bulb, with little actual advance; in others, the effects of the thrust being confined by bordering mountain walls, and thereby concentrated on the frontal end, there was notable advance of the terminus. Such an advance is best illustrated in the Hidden Glacier, whose front was pushed forward about two miles; and where the ice front stood in 1906 the glacier was 1,100 feet thick after the advance. During a brief, spasmodic advance, at least a third of a cubic mile of ice moved beyond the 1906 front; and great volumes of ice were also added to the glacier back of the old front, for in 1909 the glacier surface rose to a far greater height than in 1905 and 1906.

The theory put forward to account for this series of glacier advances is that the vigorous earthquakes of September, 1899 shook down such great avalanches of snow, ice and rock in the glacier reservoirs as to necessitate a wave of advance that swept down through the glaciers, reaching the

terminus of the smaller ice tongues very quickly, and the larger ones at later dates, while up to the period of our last observations, in 1910, the very largest glaciers had not yet responded. Since the cause was a sudden and concentrated addition of large supplies to the glacier reservoirs, the resulting wave was naturally rapid in its passage, and it quickly subsided, while its effects in passing were both spasmodic and extreme.

A study of four seasons discovers only evidence favoring this theory, and since it is an efficient cause, known to have been actually present, while no facts are known to oppose it and a great number favor it, I feel convinced that the earthquake avalanche theory merits the wide acceptance that it has received. It adds a new, and, in favorable regions, probably a very important cause for fluctuations in glacier margins. How widely it may be extended in explanation of other glacier advances remains to be established by future studies; it is not to be expected that it will replace the theory of climatic cause for glacier fluctuations; but it may well be expected to supplement it and perhaps in part replace it in regions of frequent earthquakes.

Local Nature of Recent Great Advances

It is too early to attempt to explain all the known variations in Alaskan glaciers, for as yet the body of fact is limited both as to time and as to area. Yet there are some significant features that are well worthy of consideration. Attention has already been directed to the fact that there has been a very great recent recession of the ice fronts in Glacier Bay and a similar recession in the Yakutat Bay region 150 miles to the northwest. This recession, which has been in progress for the past century or more, is really but part of a cycle in which the glaciers are still receding toward

a former minimum. Having at an earlier period been far advanced, and having held this position for a long time, the glaciers in both regions receded to a stand even farther back than the present ice fronts, and remained there long enough to permit the growth of mature forest; then came an advance pushing the ice fronts forward from 20 to 50 miles. This advance is known to have been of brief duration, for the gravels over which the glaciers advanced were not removed by the ice erosion; and it was quickly succeeded by the rapid recession that has been in progress during most of the period of observation.

So great an advance, followed by so great a recession, might be expected to be part of a general cycle affecting all or a large part of the Alaskan field. Yet such is not the case, for in Prince William Sound, 250 to 300 miles to the west of Yakutat Bay, the recent glacier history has been wholly different. In no case have the glaciers recently had a position far beyond their present fronts, while in some cases it is certain that they are to-day as far out as they have been in a century or two. This is especially clearly seen to be the case in Columbia Glacier, which in 1909 and 1910 was advancing into and destroying a mature forest. Forest also grows on the mountain slopes above the glacier for many miles back from its front, suggesting that this glacier is now in a state of unusual advance analogous to that experienced a century or more ago by glaciers to the southeast. Since there is no reason to suspect that a *general* cause which was operating to bring about glacier advance in the Alaskan coastal region could suffer retardation of a full century in the Prince William Sound region, we are forced to the alternate view that even such great advances and recessions as those proved for the Yakutat and Glacier Bay regions are

localized phenomena. Whether due to uplift or depression, to vigorous and repeated earthquake shakings, or to local climatic variations remains yet to be determined.

Cause of the Recent Retreat of Muir Glacier

It has been a generally favorite theory that the remarkable recession of Muir Glacier since 1899 is an indirect result of the great earthquakes of September, 1899. Latterly it has been proposed that the recession is due not to this cause, but to the enlargement of ice area exposed to the sea water and consequently to wastage by ice-berg discharge. Neither of these theories, nor the two combined, are either competent or needed to explain the phenomena of recession, though doubtless each has been a factor in it. Granting the maximum disturbance by earthquake shaking, and granting even that the glacier could be broken from surface to bottom, which is highly improbable in view of the nature of ice under pressure, the cracks would certainly heal and the ice become welded in its lower portions soon after the breaking. There would be no basis for the continuation of the effect of the earthquakes for a number of years after the shocks themselves had died out; yet recession has continued for twelve years after the earthquakes. Moreover, recession began many years before the earthquakes, though the rate has been much increased since 1899. As to the theory that the recession is due to the enlarged area of ice exposed to salt water, that is surely an efficient aid in recession; but it does not account for the continuation of notable recession of other glaciers in the region which now have less, rather than greater, area exposed to the salt water. Nor does it account for the excessive wastage along land margins and on ice surfaces back from the fronts.

In view of the fact that the glaciers of Yakutat and Glacier bays have been in a state of rapid recession for a century or more, all that is necessary in explanation of the recession since 1899 is to consider it an accelerated part of this grand retreat which must be due to a deficiency of snow supply following an excess in supply, or an emptying of the glacier reservoirs succeeding a filling of them. Of course, the rate of recession may readily have been temporarily modified by crevassing due to earthquake shaking, or locally modified by variation in exposure to wastage, or checked or increased by variations in precipitation or temperature. These, or any other temporary or local causes, are but minor episodes in the general withdrawal of glaciers which a century or two ago had, for some reason as yet unknown, been made to advance farther than they could maintain their fronts.

Some of the Factors Involved in the Phenomena of Advance and Retreat

Under the simplest of circumstances the advance or retreat of a series of glaciers is a complex phenomenon in which so many factors are involved that a full analysis of them can not be undertaken here. Yet some of the factors stand out with such distinctness that I may take time to briefly point them out. The nature of the glacier terminus is of fundamental importance. If the end of an ice tongue is in water it makes a great difference in the rate both of advance and recession whether the water is salt or fresh, whether it is deep or shallow, whether it is in active movement or is quiet, whether there is or is not a free escape for the icebergs, and whether the relative area of ice cliff is small or great. All these factors are effective in addition to the rate of supply of ice to be discharged. If, on the other hand, the ter-

minus is on the land, there are influences of exposure, of elevation, and of amount of moraine cover, as well as the amount of ice supplied.

Illustration from Yakutat Bay

It is clear that there must be a very great difference, especially in recession, according to whether the ice front is on the land or in the sea, for in the latter position wastage is far more rapid than in the former. This finds clear illustration in the Yakutat Bay region, for during the recent great expansion of the glaciers, a century or more ago, not only were the tidal Nunatak, Turner and Hubbard glaciers caused to advance, but the glaciers ending on the land also pushed forward, presumably at about the same time. Along the margin of Malaspina Glacier, for instance, the same phenomena of overridden gravels and buried forests are discovered as in the area over which Nunatak-Hidden Glacier advanced. But while the tidal glaciers have receded 10 to 20 miles, the recession of Malaspina Glacier has been, at the most, but a fraction of a mile; and in some parts of its moraine-covered margin, on which forest grows, it has remained practically stationary for at least half a century. This extreme difference may possibly be in part due to a more constant maintenance of the ice supply in the Malaspina Glacier, though of this there is no proof; it certainly is *partly* due to the difference in rate of recession of glaciers terminating on the land and in the sea.

Modification of Local Climate as a Result of Advance and Retreat

In interpreting both the cause and the rate of advance or recession of glaciers it is evident that the mere fact of advance encourages advance, while recession encourages continuation of recession. When

a glacier advances, the area of ice surface is increased, and its level rises, while with retreat the glacier surface is lowered and the area of ice is decreased; and if the terminus is in the sea there is a variation in the amount of floating ice with advance or recession. These changes produce a very pronounced effect on local climate, influencing both snowfall and ablation. Though the extent of the influence is naturally variable, it is roughly proportionate to the amount of the advance or retreat and to the area and height to which the variation extends. Other things being equal, the influence of an advance in encouraging advance is greater and more prolonged when the ice ends on the land than when its terminus is in the sea; for on the land the ice spreads farther and remains in position longer. Thus the climatic influence of the last advance of Malaspina Glacier is still dominant, while that of the neighboring Hubbard Glacier has been very greatly reduced by its notable recession.

In illustration of these principles it may be stated that photographs of Hidden Glacier, which in the interval between 1905 and 1909 had advanced two miles and had become greatly thickened, show a very notable difference in the amount of snow on and above the ice. This is undoubtedly due to the double cause of greater snowfall and decreased melting, brought about by a modification of the local climate as a result of the advance. At Muir Glacier, which in the interval between 1892 and 1911 has suffered such excessive recession and lowering of its surface, the climatic difference is also distinctly noticeable in photographs, but with results of exactly the opposite kind. Here there is a smaller area of ice, the surface of that which remains is much lower than formerly, a larger proportion of the sur-

face is covered with moraine or discolored by débris, and the snow-covered area on the mountain slopes is greatly diminished. Without doubt the depth of annual snowfall is markedly decreased, while the amount of ablation is notably increased in 1911, as compared with 1892. Thus when a deficiency of snowfall, or other cause gives rise to a recession, the rate of ablation may come to be considerably in excess of the amount by which the ice supply is deficient, and the rate of retreat therefore may become much more rapid than would be expected from the mere difference in ice supply.

Recession Following Advance

The problem of advance and recession is still further complicated by the apparent manner in which glacier advances take place. As shown by Finsterwalder and others,¹⁶ the Vernagt Glacier of the Tyrol responds to climatic variations by the passage through the glacier of a wave which causes the terminus to move forward, the forward movement being concentrated in a brief period of time. Other glaciers, in the Himalayas, in Patagonia and in Spitz-

A.-V.*, Jahrgang 1900, Nr. 4; "Einiges über den Vernagtferner," *ibid.*, Jahrgang 1902, No. 18; "Tiefbohrungen auf dem Hintereisferner," 1902, *ibid.*, Jahrgang 1902, Nr. 21; "Tiefbohrungen am Hintereisferner im Sommer 1908," *Zeitschrift für Gletscherkunde*, Band III., 1909, pp. 232-236; "Tiefbohrungen am Hintereisgletscher," 1909, *ibid.*, Band IV., 1909, pp. 66-70; Hess, H., "Zur Mechanik der Gletschervorstosse," *Petermanns Geogr. Mitt.*, 1902, Heft V.; Hess, H., "Probleme der Gletscherkunde," *Zeitschrift für Gletscherkunde*, Band I., 1906, pp. 241-254.

bergen, whose ends have been rapidly and notably pushed forward are apparently illustrations of the same principle; and because of the peculiar nature of the cause for the wave, the Yakutat Bay glaciers furnish illustrations of an even more spasmodic movement, and a more rapid subsidence of the wave of advance. There are many instances of minor, or minute, advances of glacier fronts; and we also know of a number of cases of noteworthy advances in Alaska and elsewhere. The more notable advances seem to be illustrations of the same principle, that a wave of advance, concentrated on the terminus of the glacier, pushes it far forward; then follows a relative deficiency of supply and consequent retreat. In the recently advanced glaciers of the Yakutat Bay region the subsequent deficiency has been so great that stagnation has immediately followed advance.

We have not yet large enough body of fact to warrant the statement of a law, but such knowledge as we possess indicates that there is reason to expect relatively rapid recession following an advance, because a deficiency of supply follows as a necessary result of the utilization of a part of the ice supply in the progress of the wave of advance. In other words, the reservoir is temporarily depleted by the drain upon it during the advance.

FORMER GLACIATION

The major part of this address has been devoted to the existing glaciers and their recent history, for this has been the field of my most extensive study. But little time remains for a consideration of the former glaciation, and what is said must of necessity be brief, and must deal with only the most general and fundamental points.

Extent of Former Glaciers

It is now a well-known fact that in recent geologic time there has been a very notable expansion of Alaskan glaciers both along the coast and in the interior. The fiords of southeastern Alaska were filled with ice to their seaward entrances, and the same was true as far west as the Alaska Peninsula. Thus there was a vastly greater ice-covered area on the seaward side of the coastal mountains than now exists there. In the interior there was also notable expansion on the inner side of the coastal mountains, on both sides of the Wrangell and Alaska ranges, and in the Endicott Mountains. Elsewhere in the mountains of the interior, even where now there are no living glaciers, there were valley tongues, and perhaps even expanded piedmont bulbs. All this glaciation was, however, purely of the mountain type, and far the greater part of Alaska was untouched by it.

Along the coast there were extensive piedmont glaciers, and there were vast piedmont ice sheets filling the fiords to a depth of several thousand feet, overflowing the low islands and peninsulas now separating them, and discharging icebergs into the ocean. Piedmont glaciers also developed along the inner face of the coastal mountains and on both sides of the Wrangell Mountains, and the Alaska Range.

By far the greatest area of ice in the interior was that which, in its maximum stage, nearly or quite filled the great basin that lies between the coastal mountains, the Wrangell Mountains and the Alaska Range, forming a great *intermont* glacier by the junction of a series of piedmont glaciers. The exact extent and the characteristics of this glacier are not yet determined; and it is not certain that it filled the entire Copper River Basin, though it

probably did, and even extended into the Susitna Valley.

Deposits of Former Glaciers

The deposits of this former glaciation are not usually extensive among the mountains, whence they have easily been removed by subsequent denudation; nor are they very notable in most places along the coast, for there the greater portion of the deposits doubtless lies beneath the sea. Only in a few places, as in the foreland that skirts the seaward base of the Fairweather Range, is there an extensive area of deposit above sea level; elsewhere the general scarcity of glacial deposit is usually striking.

In the interior, on the other hand, and notably in the Copper River Basin, there is a remarkable development of glacial and glacio-fluviatile deposit formed during the period of glaciation and during its stages of advance and of recession, of which the present must be considered a part. Here one finds the greater number of glacial features common to an area of continental glaciation—lake and glacial stream deposits, loess, till, eskers, kames, moraines, and marginal channels are found in perfect development over a wide area. One familiar with glacial deposits in Europe or America finds himself quite at home in the Copper River Basin.

The Period of Expansion

There has not been enough study of the glacial deposits to render it possible to state whether the history of the glaciation in Alaska presents the same complexity as that observed in Europe and eastern America; nor can it even be assumed that the Alaskan glaciation was contemporaneous with the glaciation of these lands. Yet, although very extensive glaciers still exist in Alaska, and although these are certainly

the descendants of the former expanded glaciers, it is entirely possible that the time since the maximum expansion is as great as that in other northern lands, such as Norway and Scotland. I can see no noticeable difference either in the extent of post-glacial denudation, or in the weathering of glacial deposits in Alaska and the Alps, or Norway, or Scotland. The greatest expansion of Alaskan glaciers certainly occurred many centuries ago, and may well have been as long ago as the time when the glaciers of the Alps shrank back into the mountain valleys. The vast work performed by glacial erosion in the Alaskan fiords clearly proves that the period of expansion of glaciers was of long duration.

Difference in Extent of Recession

There is one very puzzling condition that renders the solution of the problem of the time of maximum expansion difficult to solve. In southeastern Alaska and in Prince William Sound the tidal glacier fronts now lie from 75 to 100 miles farther back than they were in the period of greatest expansion, and vast areas of land and water have been uncovered by the recession of the glaciers. So also there has been a very large area uncovered by glacier recession in interior Alaska. But in the coastal area between Cross Sound and Prince William Sound, the glaciers of to-day appear to be only slightly less extensive than they were at the maximum. According to G. C. Martin,¹⁷ the present surface of Martin River Glacier is only 600 or 700 feet lower than during the maximum glaciation, while Bering Glacier is only about 200 feet lower; and the horizontal extension of the glaciers at the period of maximum expansion was only very slightly beyond the

¹⁷ Martin, G. C., "Geology and Mineral Resources of the Controller Bay Region, Alaska," Bull. No. 375, U. S. Geol. Survey, 1908, pp. 50-52.

present borders. Malaspina Glacier has shrunk more than the Bering, but even this is far nearer the maximum than the glaciers of Prince William Sound toward the west, or those of the Inside Passage to the southeast, or those of the interior to the north. In the same region with Malaspina Glacier, the expansion of the Nuntak-Hidden Glacier, of a century or more ago, extended to within 10 or 15 miles of the earlier maximum.

From these facts it is evident that locally, near the center of the coastal area of Alaskan glaciation, the present day glaciers are only a little short of their former maximum. This may be due to recent extensive uplift of the mountains in which these glaciers have their source, or to other local causes; or the entire history of Alaskan glaciation may be related to changes in elevation, and wholly unrelated to those causes that gave rise to the development of continental glaciation in Europe and eastern North America. We are not now in possession of a sufficient body of fact to warrant further discussion of this problem.

CONCLUSION

This brief analysis makes it clear that up to the present time only a beginning has been made in the research in the field of Alaskan glaciers and glaciation. Enough has been done, however, to show the existence of interesting and important problems, to permit a few of them to be set forth in concrete form, and to discover facts that have a bearing upon some of them. But there is so much yet to be learned, so many more facts are needed, there is so wide a field that is wholly unknown, and the period of observation is so limited that any one who undertakes to consider the general problems of this broad and complicated field can not but feel appalled at the limitations surrounding his

attempt. At best, with all the help that he can obtain from the work of others, he can only hope to make a step toward the understanding of the conditions and problems of this great field. I do not delude myself with the belief that in this address I have done more than this.

RALPH S. TARR

CORNELL UNIVERSITY

PROFESSOR GEORGE DAVIDSON

IN San Francisco on December 1, 1911, Professor George Davidson quietly ended a long life of active and valuable service to his country. Men of science the world over are expressing their sorrow at his passing, but everywhere there swells also the strong note of pride and satisfaction in the magnificent example which he has given of what may be accomplished by the devotion of a clean, strong life to a chosen field of work. Beginning his independent scientific observations in 1843 as magnetic observer for Girard College, he devoted sixty-eight years of virile manhood to geodesy, geography and astronomy. For fifty years of this long period he was uninterruptedly in the service of the United States Coast and Geodetic Survey. Three years after his retirement in 1895 from the survey he was elected to the professorship of geography in the University of California, with which institution he was connected to the time of his death. This change in his nominal employment made, however, no serious break in the continuity of his life of study and research. The exceptional character of his mental and physical virility is strikingly shown by his election to the faculty of the University of California at the age of 73—eight years beyond the limit usually fixed for the retirement of college professors.

Few men can read the brief sketch which follows without some feeling of surprise that the life of a contemporary should reach so far back into the history of another generation. Born in Nottingham, England, on May 9, 1825, in early boyhood he was brought to the United States by his parents, who settled in

Pennsylvania in 1832. He was educated in the Central High School of Philadelphia, an institution which by the school organization of that time was entitled to confer college degrees and which had an able corps of instructors. Among the faculty was Professor A. Dalles Bache. Professor Bache's high regard for the young student led to his appointment, in 1843, as magnetic observer at Girard College. Meanwhile Professor Bache was made superintendent of the United States Coast Survey and in 1845 young Davidson, then only 20 years of age, was appointed as clerk and computer to serve in the office of the superintendent. This appointment determined his life work, for he remained in the service just one half century. In 1850 at his request he was assigned to duty on the Pacific coast, where for the next ten years he surveyed harbors, selected sites for lighthouses and determined geographical positions along the coast from San Diego to Puget Sound. This pioneer work was of the greatest importance to navigators, his observations during this period being the foundation for his "Coast Pilot or Directory of the Pacific Coast," the first edition of which appeared in 1857.

At the outbreak of the civil war he was assigned to the Atlantic coast, where he was first employed as engineer on the defenses of the Delaware River. In 1862 he was in charge of the Coast Survey steamer *Vixen*, detailed for special naval service along the Florida coast. The next year, when Lee invaded Pennsylvania, he was made assistant engineer of Philadelphia.

The frequent connection of Professor Davidson with important events in the history of the United States is well illustrated by his assignments for the year 1867. In January he was detailed on duty as engineer of a party sent to the Isthmus of Panama to search for the best location for a ship canal. A few months later he was in Alaska making a preliminary geographical survey of that territory, the purchase of which was then being negotiated by the United States. His report on Alaska met the warm approval of Secretary of State Seward, and greatly influenced the

consummation of the purchase. One rare accomplishment of Professor Davidson was his ability to do reconnaissance quickly and effectively—an especially valuable quality for a man doing scientific work in a new country.

In 1868 he was promoted to charge of the United States Coast Survey on the Pacific coast, a position which he retained until June, 1895. This period was in many ways the richest and most productive of his life. He not only directed the work of the various field parties and personally made some notable geodetic and astronomical surveys, but he also served on government commissions in various parts of the world.

In 1872 and again in 1884 he was appointed by the President upon the Assay Commission to test the weight and fineness of the coins of the Philadelphia Mint, and in both instances made all the weighings and introduced new methods. Twice he was appointed by the Secretary of the Treasury to examine the assay, coin and bullion weights and the balances and beams of the United States Mint at San Francisco.

In 1873 he was appointed by President Grant one of the three commissioners of irrigation of California, and in the following year was sent to China, India, Egypt and Europe to examine and report upon irrigation and reclamation works. In 1888 President Cleveland appointed him a member of the Mississippi River Commission. In 1889 he was appointed by President Harrison a delegate to the International Geodetic Convention at Paris, and was commissioned to bring to Washington the international prototypes of the standard meter and kilogram. While abroad on this mission he visited the observatories of Paris, Berlin and Greenwich, and was received with high honors.

Many scientific societies have elected him to membership: Bureau des Longitudes de France; honorary member Berlin Geographische Gesellschaft; Royal Geographical Society; Scottish Royal Geographical Society; Swedish Society of Anthropology and Geography; Paris Academy, Institut de France; the Philadelphia Academy of Science in 1853;

of the National Academy of Science in 1874, and many others. He was president of the Geographical Society of the Pacific since its organization in 1881. He received the degree of Ph.D. from Santa Clara College in 1876; Sc.D. from the University of Pennsylvania in 1889, and LL.D. from the University of California in 1910. Norway conferred upon him the Cross of the Royal Order of St. Olaf in 1907, and the American Geographical Society awarded him the Charles P. Daly medal in 1908.

In California he was frequently called upon to give advice in the great engineering problems of San Francisco and of the state. He served as regent of the University of California from 1877 to 1884, and was a member of many state commissions. It was largely through his suggestion and influence that James Lick finally decided to build and endow the great Lick Observatory.

Professor Davidson is also favorably known for his accurate astronomical work. He was in charge of the solar eclipse expedition to Alaska in 1869 and took his 6½-inch equatorial to the top of Santa Lucia (over 6,000 feet) to observe the total eclipse of 1880. He had charge of the American Transit of Venus Expedition to Japan in 1874 and of the party to New Mexico for the transit of 1882. The Davidson Observatory in Lafayette Park, San Francisco, where he made many valuable observations, was established and maintained by him for twenty years. His remarkably fine drawing of Saturn is a monument to his acute eyesight and to his delicate skill in delineation.

The name of Davidson is inseparably connected with the foundations of accurate map work in the state of California. His long study of the coast line is embodied in the many survey charts and in the final edition of his "Coast Pilot," which was published in 1889. The north-flowing current now known as the Davidson inshore eddy, was discovered by him and studied particularly in regard to its effect upon harbor improvements.

The only base lines in California, the lines upon which all the distances involved in the extensive triangulation of the state depend,

were located and accurately determined by Professor Davidson, the Yolo base line being twice measured by him in 1881 and the Los Angeles base line three times in 1888-89. A recent report of the Coast and Geodetic Survey puts the probable error in this work as about the one-ten-thousandth part of one per cent. The location of the northeastern boundary line of California, the 120th meridian, was finally determined by him in 1873, and the diagonal boundary of 405 miles from Lake Tahoe to the Colorado River was located and marked under his supervision in 1893. This line is interesting because at each end it terminates in a body of water.

This fragmentary account affords but an imperfect idea of the breadth and scope of the work of Professor Davidson. The fact that in all the many problems of his main work his scientific accuracy stands practically unchallenged is due to his wonderful capacity for untiring effort, to his acute eyesight as an observer, and to his fixed habit of patiently and conscientiously verifying every observation.

In the seventies, when reoccupation of some of his old stations by later parties threw some doubt on his observations fixing the exact position of Mt. Tamalpais, he boldly asserted that his work was right, that the mountain might have moved, but that he had correctly determined its location at the time. After the earthquake of 1906 there was made a careful and extensive survey of central California, which, compared with the surveys before and after the earthquake of 1868, confirmed the accuracy of Professor Davidson's original observations and also his explanation of the apparent discrepancies.

Simple and unassuming in appearance, he bore the mark of one accustomed to command, and possessed a strong and dominating personality. The men who served under him learned at once to obey unquestioningly his slightest order, yet his warm-hearted and generous nature caused them to be strongly attached to him. It has been said that his life work extended through sixty-eight years of active manhood, and rightly so, although one in-

firmity partially disabled him in later years. He was made professor emeritus in 1905 and freed from any obligation to do university work, yet he voluntarily continued his classes for two years in spite of failing eyesight. The necessity of submitting to an operation for cataract finally compelled him to give up lecturing. Although the operation was but partially successful, several papers were prepared by him in these later years. Professor Davidson's indomitable will kept him at work when he was able to read only through a narrow slit in blackened cardboard under favorable light and with the help of the strongest glasses.

Under such circumstances he wrote and published in 1908 his paper on "Francis Drake on the Northwest Coast of America" and, in 1910, the paper on "The Origin and Meaning of the Name California." Both these papers necessitated the careful reading of old maps and manuscripts and yet every point was verified and compared in his manuscript and also in final proof with his original source of information.

To the last he stood as erect as a young soldier, and his voice rang with the courage that he never lost. To those who knew him personally his memory will be treasured because of his warm heart and manly character. The record of his life is an inspiration toward untiring conscientious scientific work.

RULIFF S. HOLWAY

MUSEUM EXTENSION WORK IN CHICAGO

THREE years ago the Chicago Academy of Sciences undertook an educational and museum extension policy which was new in that city. The work has been done in cooperation with the public and private schools of the city. Nearly one hundred museum loan collections have been prepared for distribution among the schools. During the year 1911, 279 loans were made to 44 different schools. Each collection thus loaned was used with at least fifty children and, in many cases, with several hundred children before it was returned to the academy. It is estimated that in this way the loan collections have been used dur-

ing the past year with upwards of 20,000 children.

Instructional courses were offered at the academy free of charge to the children who wished to come. These classes were so crowded that a delegate plan was devised which is probably unique in museum work. Each school room of a given grade may select a representative and that representative comes to the academy as a "little reporter." With note-book and pencil in hand, and with ready questions, these "reporters" make every effort to be well prepared to transmit to their classmates the lessons of which they have had the advantage. In this way the instructional work of the academy has been reaching thousands of children in the public schools each week. Fifty-six schools were represented by 553 delegates in the instructional courses at the academy. Through this method of representatives from the different classes, the work of the academy during the past year has been reported to many children.

Instructional courses to teachers were given. Some of these courses were in the laboratory and others in the field. The teachers were organized into groups to carry on special studies in the plant and animal life of the Chicago region. The study of birds and wild flowers were perhaps the most popular courses thus undertaken.

The transition of the academy from a natural history museum, organized chiefly for the benefit of its members, to an active educational institution conducted chiefly for the benefit of the community, has been carried on under the leadership of the president, Professor T. C. Chamberlin, head of the department of geology at the University of Chicago. The educational work was entrusted, three years ago, to Dr. Wallace W. Atwood, who has had immediate charge of the development of this phase of museum extension work and has organized the various courses of instruction and the methods of taking the museum to the people and especially to the children in the schools. Mr. La Verne W. Noyes, president of the board of trustees, has taken an active interest in the development of this

phase of the instructional work of the institution and has made many suggestions which have proved successful. The latest plan in museum extension work is the preparation of special museum loan exhibits. One of these special exhibits has just been prepared and is ready to be placed in the public schools, park houses, social settlements and branch libraries. The exhibit is entitled "Birds Wintering in the Chicago Region." The foreground is a miniature reproduction of the shore of Lake Michigan. Eleven birds are placed in the foreground and, by means of an oil painting, the scene is carried far into the distance. This is a type of habitat group which will be distributed and loaned free of charge. In this way a modern piece of museum work will be taken to many who may not have an opportunity to visit the main building. The ideas of museum extension is being taken up by various other organizations in the city. The Woman's Club has installed civic and health exhibits in the public schools. The social settlements, the School of Civics and Philanthropy, Municipal Art League, Council for Museum and Library Extension, are all at work on plans for special exhibits at educational centers. This is a period of unusual activity in this field and the recent gift of Mr. N. W. Harris of \$250,000 to the Field Museum will make possible still larger development of this movement in Chicago. The influence of this activity within the city is being felt throughout the state and many calls are received from rural districts for museum loan collections. The Illinois Audubon Society has made some provision for meeting this demand throughout the state. It has in constant use four traveling libraries, four bird-picture collections and two lantern-slide collections with accompanying lectures. These are distributed free of charge. The Chicago Child Welfare Exhibit has aroused wide-spread interest in the preparation of special exhibits for educational purposes.

THE AMERICAN MUSEUM OF NATURAL HISTORY

THE forty-third annual meeting of the trustees of the American Museum of Natural

History was held Monday evening, February 5, 1912, at the Union Club, where the trustees were the guests of Mr. Thomas DeWitt Cuyler, of Philadelphia.

The following were elected officers for the ensuing year:

President—Henry Fairfield Osborn.

First Vice-president—Cleveland H. Dodge.

Second Vice-president—J. P. Morgan, Jr.

Treasurer—Charles Lanier.

Secretary—Archer M. Huntington.

The president presented his annual report and announced the gift to the museum of the Catlin collection of Indian paintings, which was presented by Mr. Ogden Mills, and the Bailey collection of meteorites, which was the gift of Mr. J. P. Morgan, Jr.

According to the president's report, the total attendance for the year was 724,141, which is 100,000 greater than the attendance of last year; the number of pupils studying the circulating collection was 1,253,435, an increase of 800,000 over 1910; the membership has been increased by the enrolment of 349 new members.

Plans are being formulated for the celebration of the fiftieth anniversary of the founding of the museum, on April 6, 1919.

A comparison of the expenditures for the year shows that while the city's contribution was \$189,757, the trustees and the friends of the museum contributed \$216,404.

The building plans for the future include the construction of an east entrance hall on Central Park West and an entrance hall opposite 79th Street on Columbus Avenue. The future exhibition halls that are under consideration are the

Geographic Hall, East Wing, First Floor,
African Hall, East Wing, Second Floor,
Oceanographic Hall, Southeast Wing, First Floor,
Whale Court, Southeast Court, First Floor,
Ichthyology Hall, Southeast Wing, Second Floor.

The president emphasizes the necessity of increasing the present endowment fund.

Election to Membership: Mr. Ogden Mills was elected an associate benefactor in recognition of his gift of the Catlin collection of Indian paintings. Mrs. Isaac M. Dyckman was elected a patron in recognition of her con-

tribution for the preparation and publication of a bibliography on fishes. The Duke of Bedford was elected a fellow for his generosity in presenting to the museum two fine examples of the Prjevalsky horse, a species which has hitherto been unrepresented in the collections. Mr. Anthony R. Kuser was elected a fellow in recognition of his offer to present to the museum a collection of pheasants of the world. Lieutenant George T. Eminons was made an honorary fellow in recognition of his services in furnishing information in regard to the Indians of the Northwest Coast and in promoting field work in this region. Mr. George Bird Grinnell was elected an honorary fellow in recognition of his services in the development of the museum's department of anthropology. Sir Ernest Shackleton was elected a life member in recognition of his splendid achievements in the field of exploration, as well as for his generosity in presenting to the museum a collection of minerals from the south polar region. Dr. Leonard C. Sanford was made a life member in recognition of his generosity in placing his superb collection of birds of the world at the disposal of the curators of the museum for study and reference.

CATLIN PAINTINGS

George Catlin was the first great Indian painter and writer. He was born in Wilkesbarre, Pennsylvania, in 1796, was educated as a lawyer, but in 1823 gave up the profession for art, opening a studio in Philadelphia. A few years after he painted the famous portrait of Mrs. Madison and that of Governor De Witt Clinton, now hanging in the City Hall of New York. He early became a miniature painter, a collection of his works being in the hands of a private collector in Minnesota. Once a delegation of Indians passing through Philadelphia on the way to Washington so impressed Catlin that he planned to travel and paint the various wild tribes. Accordingly he set out and spent eight years, during which time he visited forty-eight different tribes, making portraits and sketches of scenes from daily life. Some years afterward he issued

a large illustrated work on the North American Indians which is still one of our most important publications. Mr. Catlin died in New York City in 1872, leaving in the hands of his daughter, Miss Elizabeth W. Catlin, a large collection of paintings and sketches, which has just been acquired by the museum.

This collection, comprising some 350 oil paintings, represents chiefly the tribes between the Mississippi and the Rocky Mountains as observed during the years 1832 to 1840. Many of them are the originals for the plates in the author's well-known books. Their historic value is very great, as they are the earliest authentic sketches representing the costume, ceremonies, habitations, etc., of the wild tribes. At the time Catlin visited these tribes they were practically uninfluenced by civilization. A well-known artist says: "This collection is by far the most interesting and complete in existence and for the Indian artist is invaluable, the subjects represented covering the entire life, costumes, ceremonies, etc., at a time when Indian life was real, that is, before the transition period in Indian history. I have known Indians for forty years and have seen many who were very little influenced by contact with the white man and I can vouch for the truthfulness of these pictures. They are, outside of Bodmer's and Captain Eastman's pictures, the only record we have of the Plains Indians and are valuable as a pictorial record. I want to speak of another view which the scientist does not appreciate. These Catlin pictures are the most decorative Indian pictures that have ever been painted. There is not a picture in the collection that I would not be proud to hang on my wall. They have a grand beauty of line composition, a great harmony of tone that makes them very valuable as works of art. They have the scenic charm of a Japanese print."

Thus, Catlin may be considered the original Indian artist, the predecessor of Curtis, Schoolcraft, McKenna and Hall and a host of lesser lights. For the museum, the collection will be especially valuable, since it gives us not only highly decorative canvasses, but illustrative series which may be installed

among the ethnological collections where the various scenes will show to the visitor Indian life as it once was.

Perhaps the most unique portion of the collection is the South American sketches. Alexander von Humboldt, whom Catlin met in Europe, was so impressed with the work that he urged Catlin to spend some time traveling in South America. Accordingly, in 1852, Mr. Catlin set sail for Venezuela, from whose coast he passed into the interior and over into the valley of the Amazon. For six years he explored South America, visiting all the tribes on the Pacific Slope, wandering through Yucatan, and portions of Old Mexico and later sailing for Buenos Ayres, from whence he ascended the Parana River to the north and again traversed the entire coast line of Patagonia through the Straits of Magellan. As a result of this work we have ninety canvasses representing characteristic scenes among the natives of tropical and other portions of South America.

BAILEY METEORITES

Through the generosity of Mr. J. P. Morgan, Jr., the museum has acquired the collections of meteorites and minerals that were left by the late Mr. S. C. H. Bailey. Mr. Bailey was an indefatigable collector and exchanger in both branches of science, and his series of meteorites was known as one of the largest in private hands in the number of falls and finds represented. About three hundred meteorites were received by the museum, many of which are new to its already large collection. The most important fall represented is that known as Tomhannock, on account of its having been found on Tomhannock Creek, near Troy, Rensselaer County, New York. Only six meteorites, four iron and two stone, have been discovered within the limits of the state, five of which have been cut up and distributed throughout the collections of the world and most of the larger pieces are in European museums. The main mass of Tomhannock, however, remained with Mr. Bailey, and the museum is fortunate in coming into possession of it. It is an aerolite, or stone meteorite, which was first discovered in 1863,

but was not described until 1887, when Mr. Bailey gave it its present name. The entire original mass weighed only about three and one half pounds, was well rounded and covered with the fusion crust so characteristic of meteorites. Only about one tenth of the original mass was cut off and divided among museums. Hence the part that has now come to the American Museum is nearly nine tenths of the original.

SCIENTIFIC NOTES AND NEWS

LORD LISTER died at his home in London on February 11 at the age of eighty-four years.

At the annual meeting of the Royal Meteorological Society on January 17 the president, Dr. H. N. Dickson, presented to Professor Cleveland Abbe, of the U. S. Weather Bureau, Washington, the Symons gold medal for 1912, which had been awarded to him in consideration of his distinguished work in connection with instrumental, statistical and dynamical meteorology and forecasting.

M. MAURICE MAETERLINCK, who last year received the Nobel prize for literature, proposes to raise the sum to \$40,000, and to employ it to establish a biennial prize of \$3,200 to be awarded to the author of the most remarkable work—whether on literature, art or science—published in the French language.

SIR WILLIAM RAMSAY, for twenty-five years professor of chemistry at London University, has submitted his resignation, and the senate has resolved: "That the senate accept Sir William Ramsay's resignation with sincere regret, and desire to express to him their high appreciation of the services which he has rendered to the university both by his inspiring work as a teacher and by the great series of researches carried out by him at University College during his tenure of the chair of chemistry."

PROFESSOR RUBNER, director of the Berlin Hygienic Institute, has received the large gold Rinecker medal of the University of Würzburg.

We learn from *Nature* that the Rhodesia Scientific Association's gold medal, recently

offered for an original paper advancing the knowledge of the transmission of any insect or arachnid-borne disease affecting Rhodesia, has been awarded to Dr. Edward Hindle, Beit memorial research fellow, for his paper on "The Transmission of *Spirochaeta duttoni*."

AT the January meeting of the Chicago Academy of Sciences the following officers were elected: *President*, Dr. T. C. Chamberlin; *First Vice-president*, Professor C. B. Atwell; *Second Vice-president*, Dr. Henry C. Cowles; *Secretary*, Dr. Wallace W. Atwood.

DR. ANGEL GALLARDS, biologist, has been appointed director of the Museo Nacional, Buenos Aires, in the place of the late Professor Florentino Ameghino.

DR. FREDERIC A. LUCAS, director, has been appointed to represent the American Museum of Natural History at the Centenary of the Academy of Natural Sciences of Philadelphia, March 19-21, 1912. Dr. W. D. Matthew, curator of the department of vertebrate paleontology, has been appointed to represent the museum at the celebration of the one hundred and twenty-fifth anniversary of the University of Pittsburgh, February 27-29, 1912.

MR. FREDERIC G. HALLETT, secretary to the examining board of the Royal Colleges of Physicians and Surgeons, has left London for the United States, having been invited by the council on medical education of the American Medical Association to attend the conference on medical education to be held in Chicago on February 26, and to address the meeting on the subject of the methods of conducting examinations for licenses to practise medicine adopted by the conjoint examining board in England.

THE University of Michigan has granted a leave of absence to Professor William H. Hobbs for the academic year 1912-13. In his absence from the university, the charge of the department of geology will devolve upon Professor E. C. Case. Professor Hobbs's classes in geology will be conducted by Professor Frank Carney, head of the department of geology at Denison University. Professor

Hobbs will devote the year to study and travel abroad.

THE yacht *Anton Dohrn*, of the department of marine biology of the Carnegie Institution of Washington, will make a cruise to Andros Island, Bahamas, in April and May, the chief objects being to provide an opportunity for Dr. T. Wayland Vaughan to continue his studies upon coral reefs, and to permit G. Harold Drew, Esq., B.A., of Cambridge University, to pursue his researches upon the denitrifying bacteria of tropical seas. Dr. Paul Bartsch will also study the ecology of the molluscan fauna, and trawls with self-closing nets will be made in the deep tongue of the ocean.

THE third Hamilton fund lecture of the Smithsonian Institution was delivered by Dr. Simon Flexner, director of the Rockefeller Institute for Medical Research, in the auditorium of the U. S. National Museum on February 8. The title of the lecture was "Infection and Recovery from Infection."

DR. R. M. PEARCE, professor of research medicine in the University of Pennsylvania, gave a course of five lectures on the Hitchcock foundation, at the University of California from January 22 to 26. The subjects of the lectures were as follows: "Antiquity to 1800—The Efforts of Isolated Investigators." "The Development of Laboratories for the Medical Sciences," "Pasteur and the Rise of Bacteriology," "Present Day Methods and Problems," "Medical Research in American Universities, Present Facilities, Needs and Opportunities."

THE Ichabod Spencer foundation lectures are being given at Union College by Professor Hugo Münsterberg, of Harvard University. His subject is "Applied Psychology."

AT a recent meeting of the Biological Science Club, of Oberlin College, Professor L. James, associate professor of animal ecology, gave an address covering some phases of his special research work upon the migration of birds, carried on during the summer at Pt. Pelee, Lake Erie.

MR. CALVIN W. RICE, secretary of the American Society of Mechanical Engineers, was the guest of the student branch of the society in the College of Engineering of the University of Illinois on January 23 and 24. In an address before the members of the society, Mr. Rice emphasized the importance of every engineer being interested in the national engineering societies. Mr. Rice was entertained by the local members of the society at a dinner at the University Club in the evening of the 23d.

PROFESSOR E. H. S. BAILEY, director of the chemical laboratories in the University of Kansas, has been granted a leave of absence for the remainder of the school year 1911-12, and will leave immediately for Europe, where he will make a study of foods, investigating market conditions and food supplies.

UNIVERSITY AND EDUCATIONAL NEWS

GIFTS, aggregating \$81,291, have been announced by the trustees of Columbia University including \$30,000 from Dr. William H. Nichols for instruction and research laboratories in chemistry; \$25,000 from Mrs. Russell Sage, for the E. G. Janeway Library endowment fund at the medical school; \$15,000 from W. Bayard Cutting, to establish the William Bayard Cutting, Jr., fellowship in international law, and \$10,000 from Augustus Schermerhorn, to be expended for the current needs of the university. Dr. Theodore C. Janeway has given to the trustees the medical library left to him by his father, Dr. Edward G. Janeway.

THE completion of the half million endowment fund for Oberlin College has made possible the following additions to the college resources: the men's building, \$150,000; a new administration building, \$50,000; the completion of the men's gymnasium, \$30,000; a part payment on Keep Cottage, the new women's dormitory, of \$10,000; for higher salaries, \$200,000, and other endowments, \$60,000; thus making a total of \$240,000 for buildings and \$260,000 for salaries and other endowments. Among the donors were the following: anonymous, \$200,000; a friend, \$50,-

000; Dr. L. C. Warner, of New York City, \$40,000; Mr. and Mrs. G. N. Clark, of Evanston, Ill., \$10,000; Charles M. Hall, of Niagara Falls, N. Y., \$10,000; an eastern friend, \$12,000; Mrs. D. Willis James, of New York City, \$10,000.

TRANSYLVANIA UNIVERSITY has announced that the effort to raise a fund of \$250,000 has been successfully completed. The largest gifts aside from \$50,000 offered by the General Education Board in May, 1910, were as follows: \$30,000 from R. A. Long, of Kansas City; three gifts of \$15,000 each from W. P. Bowers, of Muncie, Ind., Geo. H. Waters, of Pomona, Calif., and J. J. Atkins, of Elkton, Ky.; \$9,000 from M. F. Pearce, of Covington, Ky., and four gifts of \$5,000 each. The remainder of the fund was provided in many smaller amounts.

CONTRACTS have been let for the erection of a new laboratory of mining engineering and a new ceramics building at the University of Illinois. Two other buildings, the commercial and the woman's building, are being constructed and plans are nearly completed for a new armory, stock pavilion and transportation building.

AT a recent meeting of the court of the Goldsmiths' Company the following grants were made to the senate of the University of London: For the building fund of King's College for Women, £10,000; for the endowment fund of Bedford College for Women, £5,000; for the building and equipment fund of the chemical department of University College, Gower Street, £1,000. The company has also made a grant of £1,000 to the National Physical Laboratory at Teddington for the equipment of the metallurgical department at that institution.

DR. ROBERT DAVIES ROBERTS, secretary of the Congress of the Universities of the Empire and chairman of the executive committee of the University of Wales, who died on November 14, aged 60, left an ultimate residue legacy to the University College of Wales at Aberystwith, to form the nucleus of a fund "to enable professors after a certain number

of years of service, say not less than ten, to be released from the professorial duties for a period of about a year, and, at any rate, not less than six months on full salary, a substitute being paid out of the income of the fund; the purpose of this release from college duties being to enable the professor to refresh his mind by travel or research or visits to other universities, and so gain fresh stimulus and equipment for his work."

THE University of Pittsburgh will celebrate its one hundred and twenty-fifth anniversary on February 27, 28 and 29, 1912. The first charter was granted to the Pittsburgh Academy on February 27, 1787. In 1819 it became the Western University of Pennsylvania, the name being again changed in 1908 to the University of Pittsburgh. Educational conferences will be held on Tuesday, February 27. On Wednesday, February 28, an historical address on "The Progress of Higher Education since 1787" will be given by Chancellor Kirkland, of Vanderbilt University. This address will be followed by the conferring of honorary degrees. In the afternoon an historical address on the University of Pittsburgh will be given by former Chancellor Holland, followed by addresses by representatives of educational institutions. On Thursday, February 29, there will be conferences of the college presidents of Pennsylvania and secondary schools of western Pennsylvania. The visiting guests will be entertained at luncheon on each day of the anniversary celebration and at the alumni anniversary banquet on Wednesday evening.

By vote of the faculty of Oberlin College, the budget for the current year contains a special appropriation to be used in defraying the expenses of administrative officers, professors and associate professors who wish to attend meetings of scientific societies and other gatherings of a professional nature. The faculty is divided into ten groups, and each has a proportionate share in the general fund.

THE inauguration of President Hibben of Princeton University will take place on the morning of Saturday, May 11.

FATHER ALEXANDER J. BURROWES, S.J., a native St. Louisian and now the head of Loyola University, has been elected president of St. Louis University, succeeding Father G. P. Frieden, S.J., who died suddenly two months ago.

DISCUSSION AND CORRESPONDENCE

PROFESSOR JENNINGS AS A BIOLOGICAL PHILOSOPHER

NOT for many a day, according to my notion, has anything more significant taken place in the biological realm than Professor Jennings's presidential address on "Heredity and Personality" before the American Society of Naturalists at its recent meeting (SCIENCE, December 29, 1911).

How splendid an era of biological achievement will have been ushered in when men of Jennings's rank shall come forth from their laboratories upon occasion and discuss, without feeling the need of apology for doing so, the infinitely large as well as the infinitely small problems of our science! This address augurs for Jennings as commanding a place in the larger biology as he now holds in the smaller.

Concerning the particular road, namely, that of genetics, by which Professor Jennings has come so near the edge of the woods of biological minutism I shall say little at this time. Rather it is about his rôle as philosopher, or better as metaphysician, that I wish to speak. In the first place I want to express my gratification at the clear evidence furnished by this address particularly, that he possesses both the aptitude and the courage to be the successor of Brooks, not merely as a professor of zoology but as an upholder of the rights and dignity of the philosophical side of biology. In the second place I am going to claim the privilege usually accorded to seniority of years and counsel Jennings against the supposed necessity of apologizing for the violation of good biological manners when he yields to his inclination to talk to fellow biologists on large subjects.

Now as to the problems raised. I do not, as already said, propose to go far into the sub-

ject matter of these at present. My chief wish is to point out what, as I see them, they are historically; and to state in language not primarily biological, but rather psychological and logical, what I conceive to be the central one among them.

When the man who is a biologist comes, as he sooner or later must come, upon the problems of the "I," the "not-I," the "self," "personality," "potentiality," and the rest, he is doomed to almost complete failure in his attempt to deal with them unless he supplements, whole-heartedly and with much pains, the methods to which he is accustomed in his usual field and laboratory researches by at least some of the methods of the introspective psychologist, the logician and the metaphysician. The main reason why this is so is that our senses and our minds are just as truly instruments of research—parts of our laboratory equipment—as are our microscopes, our mother tongue, and our mathematical formulæ. Consequently to neglect to inform ourselves somewhat as to the principles of construction and mode of working of these personal instruments is to be mere rule-of-thumb workmen, just as similar neglect of the principles underlying our microscopes and language and mathematical formulæ would make us rule-of-thumb users of these means of research. The biologist who has given no attention to the way sense perception, and imagination, and rational process enter into a laboratory investigation has no more claim to be considered a genuinely scientific biologist than has a druggist's clerk to be considered a genuinely scientific chemist.

When one passes beyond the state of the raw empiricist in the use of his personal tools of research he soon comes upon the retinue of questions raised by Professor Jennings, and finds himself face to face with such live historical questions as that of the meaning of *radical empiricism*; as that of what the real kernel of *psycho-physics* is; as that of what is actually at the bottom of the conception of "*things-in-themselves*," of Berkeley's *esse est percipi*, of Descartes's

famous *cogito dictum*, of the Schoolmen's endless troubles about *matter* and *form*, *substance* and *accident*, of the early Church Fathers' warrings over the *Logos* and the *Trinity*, of Plato's *Ideas*, of the Chinese Buddhist's *Bodhisattva*, of the Vedic poet's *deva* and *vasu*, of the Melanesian's *Mana* and of innumerable other words and phrases found wherever the deeper instincts and desires and strivings of human beings have found expression in terms that mean any thing at all to other human beings. Vital knowledge of these matters does not imply vast learning. In these days when books on all subjects under heaven are almost as abundant and accessible as the leaves on the trees nothing is requisite to make every educated person informed in these regions beyond the recognition of how vital such knowledge is, and industry, economy and discrimination in the use of his time.

So much for the historical setting of the problems. Now a little as to what, substantively, the central one among them is. It is the two-fold problem as to just how all knowledge of nature, be it ordinary or scientific, is built up, and whether there is any knowledge whatever that does not contain, on the one hand, essential elements of sense perception, and, on the other hand, essential elements that can not be derived from sense perception, but have their seat at deeper depths than sense.

All I am going to say toward an answer to this question is this: If Professor Jennings will tackle again his exceedingly interesting questions of how long a "pure line" may be, and how many knots there are in the web of organic existence, starting this time from the standpoint of the "standardized reality" suggested by me a few years ago,¹ and will work at it as devotedly as he does at problems of animal behavior and genetics, he will find no more possibility of getting into the limbo he seems to be in over reincarnation than of getting ensnared in the problem of whether there is anywhere in the universe a place in which *cubes are spherical in shape*. To be

¹"Life from a Biologist's Standpoint," *Popular Science Monthly*, August, 1909, p. 180.

more specific, he will find that in his phrase "If . . . I am a redevelopment of the characteristics of some former individual from a piece of his body," the words "I" and the group of words "characteristic of some former individual" exactly cancel each other and leave an intellectual blank, just as do the words "cubical" and "spherical" when the attempt is made to apply them to one and the same body. That is to say, despite the splendid combination of breadth of outlook and ability as a laboratory methodologist and technician which distinguishes Jennings as a biologist, his address at this point is subject to the same miscarriage of reason that has characterized nearly all modern speculative thinking on the Mendelian type of inheritance. The miscarriage to which I refer arises from neglecting the technical detail of noticing that since there always is a strictly psychological or subjective element in the idea expressed by the term "characteristic," it comes about that the very construction of the sense-perceptual aspect of our knowledge is such as to make it utterly impossible for the truly *same* characteristic to belong to more than one body. This fundamental truth has been overlooked in speculative biology largely, I suspect, from failure to note that so far as the subjective side of perception is concerned, "characteristic" is exactly synonymous with "quality" and "property." Bearing this fact in mind, the situation clears up readily when we turn to the familiar practical (not, generally, the theoretical) language of chemistry. The working chemist never for an instant thinks of trying to express or "explain" the characteristics, or properties of hydrogen in "terms of" the characteristics of oxygen, for he knows perfectly well that were he able to do such a thing there would be no such gas as hydrogen, for all hydrogen would be oxygen. There is no doubt in the world, as one sees if he looks at the case closely, that most of the recent effort to "explain" the adult organism in terms of the germ cells has involved just the self-destructive fallacy that the chemist would be a victim of were he to try to explain

hydrogen in terms of oxygen. The fact that the adult organism develops from the germ cells while oxygen does not, so far as we know, develop from hydrogen, does not in the least affect the psychological fact that the adult is known by its own characteristics and in no other way, exactly as the germ cell is known by its characteristics and in no other way.

Once one sees clearly that this aspect of the problem of genetics differs *toto celo* from the problem of developmental potentiality, that is, the problem of how the germ cell is able to develop into the adult, he has gone a very long way toward a consistent, workable philosophy of biology.

In Jennings's sentence "if the phrase 'potential immortality' means anything for the infusorian, it means exactly the same for me, so far as we can judge from past history," I find encouragement for the hope that he will be willing to give my principle of standardization a good testing.

THE CHESTNUT TREE DISEASE

TO THE EDITOR OF SCIENCE: In connection with the chestnut tree disease mentioned in SCIENCE of December 29, 1911, and in preceding numbers, the writer calls attention to the hardy giant chinquapin (*Castanopsis Chrysophylla*) of the Pacific states. This may be a resistant species adaptable to the southern states. It occurs in two varieties, the one just mentioned and a dwarfed variety. The former reaches a height of 120 feet and has a diameter of from 8 to 10 feet; ordinarily from 40 to 55 feet in height and from 1 to 2 feet in diameter. Locality, near Willets in Mendocino County, Cal. The dwarfed form is abundant in the Cascade and Sierra Nevada and San Jacinto mountains from 2,000 to 9,000 feet. It is mostly of shrubby habit, but to all appearances identical with the giant chinquapin. This latter is a hardy and long-lived evergreen of stately and handsome

form. The timber is suitable for many purposes, saws readily, is fine grained and light brown. The burr and nut of both varieties are almost identical in size and appearance with the eastern chinquapin. They are difficult to obtain and are frequently attacked by a small whitish worm, the egg of which is deposited, as in the eastern chinquapin and chestnut, by a moth.

The writer suggests that the giant chinquapin be experimented with as a possible resistant species to reforest the eastern states devastated by the chestnut tree disease. The tree would probably stand the eastern conditions south of Maryland. The shrub is extremely hardy.

MARSDEN MANSON

SAN FRANCISCO, CAL.,

January 8, 1912

AN UNUSUAL EFFECT OF A LIGHTNING DISCHARGE

THE following note made by the writer under date of July 18, 1911, may be of interest: On the land of J. M. Dunklee (of Hawes postoffice, Ark.), in the N.E. $\frac{1}{4}$ of the N.E. $\frac{1}{4}$ of Sec. 11, T. 2 S., R. 20 W., the lightning struck an oak tree (according to Mr. Dunklee three years ago), much shattering it. The tree stood near the top of a sandstone ridge. The discharge passed to the roots of the tree, then followed in the ground down the north slope, tearing out a trench in places 3 feet wide, and which must at first have been 2 $\frac{1}{2}$ feet deep. At this time, the depth is 1 $\frac{1}{2}$ feet. The discharge followed down the slope 50 feet, tearing up the sandstone and throwing one block that is estimated to weigh 1,200 pounds up into the air and out of the trench. At the lower end of the trench, the discharge apparently passed beneath the surface, along a bedding plane between the upturned layers of sandstone. There is no evidence of any fusion of the rocks or the soil.

"MISUSE OF THE TERM 'GENOTYPE'"

TO THE EDITOR OF SCIENCE: If the distinguished students of genetics whose communi-

cations have recently appeared in your pages do not imagine that their work is of interest to biologists and naturalists at large, then one is entitled to question their claim to so much of your space. Let them, one might say, confine their "terminological inexactitudes" to their own technical periodicals. If, however, they believe, as I do, that their highly valuable work should appeal to all biologists, and that it has a particularly important bearing on the methods and conclusions of the systematist, then surely they should try to avoid the use of terms that are liable to mislead the general naturalist, and that sooner or later must clash with those of the taxonomic biologist. But assuming that they persist in acting as though their work were either unworthy of general attention or far above the heads of all outside their charmed circle, still may one not appeal to them to recognize that serious writers in SCIENCE are at any rate their scientific colleagues, and as such have a claim to be treated with ordinary courtesy? To state, after what has been written, that Dr. Johannsen is the "originator of the word genotype" is to give either the cut direct or the lie direct to a fellow-worker.

SCIENTIFIC BOOKS

The Animals and Man. An Elementary Text-book of Zoology and Human Physiology. By VERNON LYMAN KELLOGG. New York, Henry Holt and Company. Pp. 495.

The present trend in high schools toward a combined course in human physiology and zoology is calling forth its inevitable train of new text-books, of which the present volume by Professor Kellogg is one. Knowing the writer's practise in text-book preparation and his wide experience as a teacher and a zoologist, one is justified in looking for something exceptional in this new effort, but the reviewer must confess to a feeling of disappointment on reading the book. It has the appearance of having been hastily constructed with a somewhat too liberal use of scissors and paste on

the author's earlier text-books. The section on human physiology (chapters XXI.-XXVIII.), by Miss McCracken, while interesting enough in itself as an abridged elementary account of human anatomy and physiology, stands almost wholly unrelated to the rest of the text. To the reviewer, the present need seems rather to be for a text-book of zoology so thoroughly permeated with physiological interpretations and applications that the zoology and physiology become a unit throughout the entire work. However, beyond the question of arrangement of material—a matter which will doubtless always remain largely one of individual opinion—the over-plentiful sprinkling of errors throughout the book lays it open to more serious criticism. For example, on page 32 in a description of the crayfish we read that "In the female the genital pores are in the basal segments of the next to the last pair of legs." On the same page *ligaments* are spoken of when *tendons* are meant, the digestive gland is described as yellow whereas it is characteristically reddish or greenish in color, and *four* pairs of ostia (a dorsal, two lateral and one ventral pair) opening into the heart are called for. On page 35 occurs a questionable usage of the term *ureters*. Again, in the light of recent investigations, we doubt if the statocyst of the crayfish is very generally "believed to be an auditory organ" (pp. 30, 74). On the same page one reads that "the longer pair of appendages are the antennæ and the sense of smell is believed to be located in the fine hair-like projections upon the joints." As a matter of fact, certain peculiar club-shaped organs on the outer ramus of the *antennules* have generally been considered the chief olfactory end-organs. Recent researches of Holmes and Homuth confirm this but show that other parts of the body (mouth parts, tip of chelipeds, inner ramus of antennules and the antennæ) are also sensitive to olfactory stimuli. On page 41 we find this astonishing statement in an account of conjugation in *Paramœcia*, "... part of the macronucleus and micronucleus of each passes over to the other, and

the mixed elements fuse together to form a new macro- and micronucleus in each half." In view of the wonderfully adapted mechanism in the amphibian heart for keeping the "pure" and "impure" blood at least approximately separated, the statement regarding the ventricle of the toad (p. 23) that "here the pure and impure blood are mixed," might well be qualified somewhat. On pages 14 and 15 *quill feathers* and *contour feathers* are set apart as two contrasting groups. On page 47 occurs the statement that "in addition to the proteids protoplasm usually contains native albumins," etc.; native albumins, of course, being proteins. Throughout the book the word *proteid* is used instead of the preferable *protein*. On page 100, speaking of the pairs of legs, the statement is made that "the order of their appearance differs in the toad tadpole and the frog tadpole." One is led to suspect that the author had in mind rather anuran and urodele tadpoles respectively. On page 153 we are inaccurately informed that "hermit crabs all have the habit of carrying about with them, as a protective covering into which to withdraw, the spiral shell of some gastropod mollusc," and in the same paragraph, speaking of the abdomen of the hermit crab, occurs the statement that "it has on it no legs or appendages except a pair for the hindmost segment, which are modified into hooks for holding fast to the interior of the shell." As a matter of fact while generally absent from the right side of the abdomen (except on the sixth somite), the pleopods of the left side, though often much reduced, are present, and in the female are used for the attachment of the eggs. On page 154 in speaking of the acorn barnacles the "six calcareous plates" mentioned are characteristic of the family *Hexameridae* only and not of all "acorn barnacles." On page 170 we are told that "the cuttlefishes and octopi have no foot," but on page 178 that "the decapods, as their name indicates, have ten feet or arms," etc. Aside from this contradiction in statement, the high school student might pertinently inquire what the

name *Cephalopoda* indicates. On page 191 it is stated that "nearly all the Chordata are marked by the presence, either in embryonic or larval stages only, or else persisting throughout life, of a number of slits or clefts in the walls of the pharynx which serve for breathing, and which are called gill-slits." Do not *all* Chordata have gill-clefts at some stage of their life history? Again, on page 201 one reads the too inclusive statement that "all batrachians breathe by means of gills for a longer or shorter time after birth." On page 256, hyenas are classified as *Felidæ*. On page 337 we are informed that muscles are the active organs of motion and locomotion in all animals.

In the physiological section there is an obvious attempt to "write down" to the audience and the result is frequently anything but happy. For instance one meets not infrequently with such apparently significant though actually meaningless statements as (p. 291) "the most necessary element in all the world is oxygen." On page 294 one encounters the rather astonishing bit of information that "muscle is largely a compound of sulphur and other elements." On page 316 we read that "it is the function of hæmoglobin to carry oxygen to the tissues and carbon dioxide from the tissues," a statement which, to say the least, is misleading, in that as regards carbon dioxide, the carrying power of hæmoglobin is at most of minor importance. On page 340 heart muscle is classified as non-striated. On page 291 we encounter the obscure and in part erroneous statement that "carbohydrates contain carbon, hydrogen and oxygen, the former predominating. Fats contain also chiefly oxygen, carbon and hydrogen, the latter predominating." On page 296 under "Tests for Proteids" what is probably the most universal and certain test of all, the biuret reaction, is omitted. On page 301 referring to alcohol we find this remarkable piece of information—remarkable both in point of fact and of rhetorical climax—"unlike other poisons its use establishes a craving or appetite for it which eventually

weakens the will and is apt to lead to intoxication." How *unlike* cocaine, opium, morphine, etc., is it in this cumulative effect? On page 311 we learn that "the mesentery is fastened at the back to the spinal column." On page 363 instead of using axon and axis cylinder as synonymous terms the axis cylinder is spoken of as a central fiber of the axon. On page 317 the term *fibrin* is misused.

A careful reading of the text discloses a considerable number of little inaccuracies, mainly in the way of too inclusive statements, but space will not permit of specific citation. Some of these may perhaps be excusable on the basis of being well-nigh unavoidable in an elementary book where confusion of ideas must be avoided, but in not a few instances a single qualifying word would have set the matter right.

While the reviewer has found it necessary to devote most of his space to pointing out errors, he does not wish to leave the impression that the book is without merit. On the contrary, it has many excellencies. The subject-matter is well chosen, the general descriptive treatment is for the most part excellent and interestingly written and the text covers a wide range of timely topics in addition to the more formal zoological work.

M. F. GUYER

UNIVERSITY OF WISCONSIN

A FEW BOOKS ON AERONAUTICS

A new science and a new industry, a new sport and a new mode of warfare have come upon us with such startling suddenness that many are clamoring to know how it all came about; while authors are tumbling over each other—many over the facts and even over their English too—in a mad rush to tell the story, the story of aeronautics that only a master can tell.

The following are a few of the 1911 versions of this story.

Aerial Locomotion. By E. H. HARPER and ALLEN FERGUSON. Cambridge University Press, XII., 164, price 1 shilling.

This little book is so clearly written that it

can be understood by the average boy, and yet it explains many facts that often are either wholly ignored or, for the average reader, told only in unintelligible symbols and signs.

For the non-mathematical reader, and for the man who does not care for a large volume on the subject, this probably is one of the best books available.

The Aeroplane. By T. O'B. HUBBARD, J. H. LEDEBOER and C. C. TURNER. Longmans, Green and Co., X., 127, price 2 shillings 6 pence.

There is an old proverb to the effect that "too many cooks spoil the broth," and it seems to be eminently applicable in the present case.

The first chapter deals with the properties of the air, and is so full of errors that it would take another chapter to correct them. A simple example will suffice:

Now the density of water-vapor is 0.623 of that of air, and since air can contain a portion of water-vapor amounting to 3 per cent. of its volume, it is obvious that saturated air is lighter than dry air.

This statement would be pretty hard to beat in a contest for number of errors in a single sentence. One had as well say that since a sponge can contain water that therefore a saturated sponge is lighter than a dry one.

As a matter of fact moist air is lighter than dry air at the same temperature and pressure, but the authors have not explained the correct reason.

The rest of the book, after the first chapter, is fairly good for the popular reader and has the excellent feature of conspicuous division into topics, but it is marred here and there by the presentation of rough approximations in the guise of exact values.

Bird Flight as the Basis of Aviation. By OTTO LILIENTHAL. Longmans, Green and Co., XXIV., 142.

This of course is a translation of an old and well-known German book. But the translation was worth while, since it enables a larger number of persons to read for themselves Lilienthal's accounts of numerous ex-

periments based upon careful studies of birds and their mode of flight. It is astonishing how many experiments he and his brother made, and what generally well-founded conclusions they reached. Otto Lilienthal was one of the enthusiastic pioneers in the experimental study of aviation and his work undoubtedly contributed materially to the final accomplishment of mechanical flight, albeit along lines different from those he believed the most practicable. He believed that nature's method is always the best method—forgetting, possibly, that the locomotive, though swifter than the greyhound, runs on wheels and not on legs—and so he strove to fly, as do the birds, with beating wings and soaring.

Soaring, at least, is greatly to be desired, and likely some day to be fully achieved, and so this book, by one of the most enthusiastic advocates of bird flight, still has a freshness about it and much of interest; in fact it is one of the few aviation classics.

Monoplanes and Biplanes. By G. C. LOENING. Munn and Co., New York, XIV., 331, price \$2.50.

This book is not adapted to the taste of the general reader—it is neither poetry nor romance—but to the man who is seriously studying aeronautics and needs to know how the various types of aeroplanes are made it is well nigh invaluable.

It begins with a short but appreciative account of the work of Langley, Lilienthal and Chanute. This is followed by several excellent chapters on air resistances and air friction, with numerical examples applicable to aeroplane designing.

After this, various types of aeroplanes, 18 monoplanes and 20 biplanes, are described in detail and intercompared. A separate chapter is devoted to the different types of controlling apparatus, and another timely and sensible chapter, to accidents and their various causes.

Every chapter is profusely illustrated, and in the great majority of cases the illustrations are extremely helpful to the reader. There also are numerous references to original articles which may be consulted by those who wish more detailed information.

In a new edition pages 18, 19 and 20, in so far as they discuss air density, might be slightly modified to advantage. Here "air holes" are spoken of as places of low air density.

An aeroplane entering one of these low density regions from the air of higher density around it, will suddenly fall without any warning, merely because the pressure has enormously decreased, and the aeroplane has not had time to attain the requisite velocity of support in this lighter medium.

Enormous differences in pressure must cause enormous changes in the barometer, but such sudden changes are never found in the open, and, besides, it can be shown that the movement (whirl) of the atmosphere necessary to produce a change of pressure amounting to one tenth of the total would be of most destructive violence.

But this is a small fault to find with a book so generally helpful.

Elementary Aeronautics. By ALBERT P. THURSTON. Whittaker and Co., 126.

This is a non-mathematical but clearly written account of the action of air upon moving surfaces, plane and curved, and the application of these principles in the design and operation of aeroplanes.

While both elementary and brief, it seems to be free from errors, and can be recommended to those who wish some reliable information about the general action of aeroplanes, but have not the time to make a real study of them. W. J. HUMPHREYS

A Manual of Philippine Silk Culture. By CHARLES S. BANKS, Department of the Interior, Bureau of Science, Manila, 1911.

Mr. Banks has been engaged, among his other duties, in a study of the possibilities in the way of profitable silk culture in the Philippines ever since the Bureau of Science was started, and this manual puts into convenient shape the results of his investigations. It is a royal octavo pamphlet of about fifty pages, with 18 good half-tone plates and diagrams of rearing house and reel. He gives directions for the care of the domestic mulberry silkworm, and announces a cross between the Ben-

gal-Ceylon and Japanese silkworms which he terms "the Philippine race of silkworms." He also announces the successful introduction of the Eri or Castor silkworm (*Attacus ricini* Boisd.) from Ceylon. He thinks that the silk produced from this insect will be popular not only among the Christian Filipinos, but also among the mountain tribes and the Moros, and further that it will find a sale among the Americans and Europeans for hangings, upholstery and even for heavy dress goods. He concludes that, with both the mulberry and the Eri silkworms, the industry can be carried on in the Philippines under conditions as favorable as those which obtain in the best silk-producing countries in the world, with the added advantage that no disease has appeared as yet. That every effort is being made to prevent the introduction of disease is shown by the act of August 14, 1907, prohibiting the importation of silkworms, either eggs or cocoons, into the Philippine Islands except by the Bureau of Science.

L. O. H.

SPECIAL ARTICLES

FOSSIL HOLOTHURIANS

Few classes of animals have a less satisfactory geological record than the holothurians and every fragment that can be gathered is therefore of unusual interest and importance. The known records occur in two forms, impressions of the whole animal or much more commonly, nearly or quite microscopic calcareous particles imbedded in fine shales and limestones and resembling more or less nearly the similar calcareous particles found in the body-wall of most living holothurians. Ludwig¹ has well summed up the phylogenetic value of these fossil particles:

Solche Reste aus dem Kohlenkalk, dem Jura, der Kreide und dem Tertiär vorliegen, aber keine sichere Bestimmung nach Art, Gattung und Familie gestatten: nur die eocänen Synaptidenreste . . . machen davon eine Ausnahme, da sie sich mit einiger Sicherheit auf die Gattungen *Synapta*, *Chiridota* (oder *Trochodota*) und *Myriotrochus* beziehen lassen.

¹ 1892, "Die Seewalzen," p. 446.

If then we are to secure satisfactory paleontological knowledge of the history of holothurians we must look for it in the impressions (or possibly casts) of the entire animal. As yet evidence of this sort is very rare and highly unsatisfactory. Rüppell¹ long ago described what he thought was a fossil holothurian from the Solenhofen limestone but there is little about either his description or figure that warrants his conclusion. Zittel² suggested that the object might perhaps be a cephalopod, but that is also little more than a guess. Giebel³ has given an account, accompanied by three good figures, of fossils from the same limestones for which he proposed a genus "Protholoturia." Zittel (*l. c.*) refers casually to this genus but considers the specimens "problematische körper." Probably he was not familiar with the appearance of living holothurians, particularly when eviscerating; otherwise it is hard to see why he was so doubtful about Giebel's specimens. Ludwig (*l. c.*) quotes Zittel but apparently without having examined Giebel's figures, which are deserving of careful consideration. Study of these figures and their accompanying text has satisfied me that the objects really are the impressions or casts of holothurians. Giebel found calcareous particles in the outer body layer (or on the surface of the object), thus confirming the impression made by the striking resemblance of the outline and surface, to contracted specimens of the smaller species of Holothuria. It seems to be impossible, however, to point out any characters by which "Protholoturia" may be distinguished from Holothuria and the name is no doubt a synonym, but it is odd that it is not listed in Scudder's Index (either as Protholoturia, Proholothuria or Protoholothuria) nor in the later generic lists of the "Zoological Record." Even Spandel and other writers on fossil holothurian remains seem to have overlooked or

forgotten Giebel's work. Simonelli⁴ figures a peculiar fossil, *Lorenzina*, which he suggests may be part of a holothurian allied to *Pelagothuria*. The material is such that no real identification is possible and the probability of its having anything to do with holothurians is very remote.

The Solenhofen specimens of Giebel therefore appear to be the only fossil holothurians known (not counting, of course, isolated calcareous particles) and obviously their phylogenetic value is slight, as they simply show that holothurians apparently like those of the present day existed in the Jurassic Seas. It was, therefore, a matter of extraordinary interest when Dr. Walcott recently announced the discovery of a notably diversified holothurian fauna in the Middle Cambrian rocks of British Columbia.⁵ Through the greatly appreciated courtesy of Dr. Walcott and the kindly assistance of Mr. Austin H. Clark, I have recently had the privilege of examining the material upon which this report is based and I will say at once that Dr. Walcott's published figures leave almost nothing to be desired. Excepting only two specimens, examination of the originals showed nothing not revealed by the figures and equally important is the fact that the figures show nothing which is not equally distinct in the specimens. This is most satisfactory, as it will enable any one familiar with the fundamental characteristics of the class to form an intelligent opinion as to whether Dr. Walcott's fossils represent holothurians or not. The two cases in which I have taken exception to the figures are found on plates ten and thirteen. In Figure 1, Plate 10, the illustration does not quite do justice to the specimen; the knobs shown above the central ring (*CR*) are more distinct in the specimen, two of them showing not only definite outlines but some indications of their structure. In Figure 2, Plate 13, on the other hand, the terminal mouth

² 1876-80, "Handbuch der Paläontologie," Bd. 1, Abt. 1.

³ 1857, *Zeitsch. f. die Gesamten Naturw.*, Bd. IX., pp. 385-388.

⁴ 1906, *Bologna Mem. Acc. Sc.*, 1905, series 6, Vol. 2, pp. 263-268.

⁵ 1911, "Cambrian Geology and Paleontology," II., No. 3, Middle Cambrian Holothurians and Medusae, *Smithsonian Misc. Coll.*, Vol. 57, No. 3.

surrounded by a jointed or notched ring is distinctly shown; in the specimen, I was unable to make out these points satisfactorily; there seems little doubt about the terminal mouth, but the surrounding ring is ill-defined and I failed to see the joints.

Dr. Walcott names and describes four genera, each with a single species, of what he believes to be holothurians. He apparently has not seen Giebel's figures for he says (p. 42) that his specimens record "for the first time, with the exception of some scattered calcareous spicules and plates, the presence of this class of organisms in any geological formation." That he feels no serious doubts as to the fossils being holothurians is shown by the statement (p. 43) that they establish "the very ancient origin of the Class Holothurioida and the fact of its great differentiation in Middle Cambrian time," and the assertion (p. 45) that "The Holothuriidæ is represented by *Laggania cambria* and *Louisella pedunculata* and the Synaptidæ by *Mackenzia costalis*. The Pelagothuriidæ is indirectly represented by *Eldonia ludwigi*." It is not clear what is meant by the Pelagothuriidæ being "indirectly represented" by *Eldonia* since that genus is subsequently made the foundation of a new family, the Eldoniidæ, especially as Dr. Walcott later shows that his new genus has almost nothing in common with Pelagothuria.

The material upon which *Eldonia* is based is abundant and much of it seems to be very well preserved, but of *Laggania* and *Louisella* there are single specimens only, while of *Mackenzia* there are but two specimens and they differ from each other greatly. Of *Laggania*, Dr. Walcott says the mouth was "ventral, near the anterior end and surrounded by a ring of plates." "It is not practicable to make out the arrangement of the plate-like structure surrounding the mouth, as the calcareous plates, if ever present, have disappeared." "Traces of tube-feet occur on the ventral surface" but "the body of the animal is so completely flattened that the tube-feet are obscured." I have sought in vain both in the figure and on the specimen for anything that could be called a tube-foot, without an exces-

sive use of the imagination. Moreover the "ring of plates" surrounding the mouth does not remind one of the calcareous ring of a holothurian, but it does suggest to me the radiating folds surrounding the partially contracted oral disk of certain actinians and worms. Dr. Walcott calls attention to the surface markings of "indistinct concentric bands, each one of which is crossed by fine longitudinal lines." This can be easily seen in the figure (at least in certain spots) with the aid of a lens. I do not recall any holothurian with such a surface, but it is suggestive of certain worms, and even some actinians have a somewhat similar exterior. On the whole it does not seem to me that *Laggania* can be positively assigned to any invertebrate phylum. I see nothing beyond the probable form of the body, and the terminal mouth, to suggest a holothurian, and these characters are equally suggestive of actinians.

The specimen of *Louisella* seems to show more structure and Dr. Walcott says of it:

With numerous tube-feet or podia in two longitudinal rows, and what may be papillæ on two peltate extensions at the posterior end. . . . The ventral sole is beautifully outlined by the marginal row of podia on each side.

Examination of the specimen (or figure) shows of course what Dr. Walcott has called the "ventral sole" and "marginal rows of podia," but neither is suggestive of any known holothurian excepting some of the bizarre Elasipod forms like *Scotoplanes*, to which Dr. Walcott refers. None of the podia are sufficiently defined to enable one to make out even the form, let alone the structure, whereas if they were really like those of *Scotoplanes* and other Elasipods, their rigidity would have caused them to be as well defined as any part of the body-outline. Dr. Walcott considers *Louisella* a genus of the Holothuriidæ, but the size and arrangement of the supposed podia are entirely unlike anything known in that family. If *Louisella* is a holothurian at all, its "ventral sole" and big podia (?) would suggest the Elasipods as its nearest allies, and the two extensions of the posterior end might be considered confirm-

atory evidence. But as there seems to be no really characteristic holothurian structure shown by the fossil, I fail to see why it should be considered a holothurian.

The small specimen of *Mackenzia* is very suggestive of a synaptid without its tentacles, but the most searching examination fails to show a single character which gives positive support to this view. The mouth and its associated structures are not distinctly indicated. As stated above, I could not distinguish any separated or definite parts in the raised ring which seems to surround the mouth, and there is nothing in it to me suggestive of the calcareous ring of a synaptid. The longitudinal markings of the body-wall are more numerous and closer together than they should be if they indicate the longitudinal muscles of a holothurian. On the whole, these longitudinal markings, the appearance of the body surface and of the oral end, and the form of the animal all seem to me suggestive of certain actinians, although I do not assert that the fossil really represents that group. The larger specimen, referred to *Mackenzia* by Dr. Walcott, shows practically no structure and in my judgment can not be assigned positively to that or any other genus.

Turning now to *Eldonia*, of which the material is plentiful and its condition such that the structure can be made out with a fair degree of completeness, we find an animal so medusoid in outer form that Dr. Walcott uses the terms "exumbrella," "subumbrella," "lobation" and "lappets" and says "the system of radial canals is very striking and medusa-like." I do not recall any medusa with a canal system like *Eldonia's*, with a small central ring, but I think most of us will agree that the general appearance of the animal is that of a free-swimming Cœlenterate, except for the apparently distinct and extraordinary alimentary canal. It is upon the interpretation given this structure and upon the importance attached to it, that our final decision as to the position of *Eldonia* must depend. Dr. Walcott at first thought it might be a commensal worm but later decided it was really the alimentary canal of the animal itself, and

upon the strength of its partially spiral form, he based his decision to call *Eldonia* a holothurian. He has, however, pointed out the essential differences between *Eldonia* and *Pelagothuria*, the only known free-swimming holothurian, making it plain that they are not at all nearly allied. Emphasis should be placed on the fact that except for the expansion of the oral disk as a swimming organ, *Pelagothuria* is not an extraordinary holothurian, its internal anatomy being like that of many other members of the class. Its alimentary canal is in loops (a long drawn out spiral) and the mouth is surrounded by the usual circle of tentacles. The alimentary canal of *Eldonia* is not in loops as in a holothurian but seems to have been more nearly in a single plane like one half of the canal of a sea-urchin. The appearance of the tube thus seems to me more echinoid than holothurioid. The mouth of *Eldonia* has on either side a large tentacle; neither Dr. Walcott nor I have been able to find more than two and the whole appearance of the oral region indicates two as the normal number. The tentacles are described by Dr. Walcott as "peltato-digitate" but they have almost nothing in common with the sort of tentacles to which that term has hitherto been applied.* On the other hand they seem to me suggestive of the marginal clusters of tentacles in *Lucernaria* and its allies. Perhaps even the oral tentacles of some Rhizostomous Medusæ are not fundamentally different. In some of the specimens, notably the one shown in Fig. 1, Pl. 10, bits of the tentacles show some slight indications of their finer structure. In the figure referred to, small lobes or knobs above the central ring (CR) are noticeable and these, in the specimen, show, under the lens, a remarkable resemblance to clusters of nettle-cells. I am not sure that these lobes are part of the tentacles but if they are, as they seem to be, my opinion that the tentacles are more medusoid than like anything known among holothurians would be confirmed. *Eldonia* shows absolutely no trace of pen-

* See Ludwig, 1892, "Die Seewalzen," p. 97; Pl. VII., Fig. 5.

tamous symmetry, no trace of calcareous structure, no longitudinal muscles and no podia. The radial canal system is utterly unlike the water-vascular system of any known Echinoderm and it is perfectly inconceivable how the fundamental, circumoral ring of a holothurian could disengage itself from the esophagus and migrate to the opposite end of the body.

If *Eldonia* is a holothurian, it becomes virtually impossible to define the class, except in terms of the alimentary canal. Indeed if *Eldonia* is a holothurian, the Echinoderms themselves can be defined in no other terms, for *Eldonia* lacks every single character which justifies the customary view that holothurians are Echinoderms. It is far less of a strain on my credulity to believe that *Eldonia*, whose extraordinary nature I have no inclination to deny, is some sort of a Cœlenterate with a commensal worm inside or under the sub-umbrella, or even that it represents a hitherto unknown phylum, than to believe that it is a holothurian or is connected, save in the remotest way, with the Echinoderms.

As a final result of my examination of the evidence, I am forced to conclude that there is no sufficient justification for the belief in a Cambrian holothurian fauna. The external form of *Louisella* and *Mackenzia* and the supposed alimentary canal of *Eldonia* can not be considered adequate basis for such a belief. There is no good evidence, either in Dr. Walcott's material or elsewhere, to show that holothurians existed before the Carboniferous. But as wheels, which are certainly of a Chiridota-like form, occur in the Zechstein of Europe, and animals closely allied to our modern Holothuria are found in the Solenhofen limestone, it is not improbable that the holothurians were differentiated about as early as the other classes of Echinoderms, excepting the Pelmatozoa. Evidence however in support of such a probability is still conspicuous by its absence.

BIOLOGY OF MIASTOR AND OLIGARCES

THE general availability of *Miastor*, at least for laboratory work, justifies the following summary account of the biology of this interesting form and the allied, possibly sometimes associated, *Oligarces*.

Distribution.—*Miastor* is probably world-wide in distribution, having been recorded from Europe, Australia, North and South America. We have found this genus ranging in New York from the upper austral Hudson valley to the transition or boreal Adirondack region. These peculiar larvæ have also been found in Connecticut and Indiana.

Oligarces has been recorded only from Europe and North America, Albany and adjacent Nassau, N. Y., being the only American localities at present known. This species is probably widely distributed though presumably rarer or less easily detected.

Larval Habits.—The moist inner bark of various trees in the incipient stages of decay are likely places for *Miastor* larvæ. Chestnut rails, ties, stumps, the moist bark of maple, oak, birch, beech and hickory indicate no closely restricted food habits. In addition to some of the above, European report *Miastor* larvæ from elm, ash, ironwood and sugar-beet residue.

We have found *Oligarces* only in decaying elm bark, possibly because the larvæ are not so readily detected in nature.

Distinguishing Characters.—Large colonies of *Miastor* larvæ are easily recognized by the masses of more or less adherent yellowish or whitish larvæ, and especially by the occurrence here and there of motionless individuals with poorly indicated segmentation and elongate, transparent areas, the developing embryos, or containing young so well developed as to be easily distinguished with a hand magnifier, even the form of the head and the fuscous ocular spot being visible. The head of these larvæ, whether small or large, is flattened, triangular with diverging antennæ and quite different from the strongly convex, usually fuscous head of *Sciara* larvæ. *Miastor* larvæ have transverse incisural bands of

chitinous spines, best developed on the anterior body segments. These larvæ are $\frac{1}{20}$ to $\frac{1}{4}$ of an inch long and may occur in small clusters in the bark or form dense masses covering several, if not a number of square inches, frequently more or less clustered and appearing much like a mass of fungous matter commonly seen under bark.

Oligarces larvæ are similar in general aspects, though we have yet to find them in any such large masses as described above. Elm bark containing this maggot gives little evidence on the inner surface of their presence, since these larvæ appear to confine themselves mostly to the interstices of the bark.

Biology.—The larvæ of both genera reproduce by pedogenesis in the fall and early spring. We have also observed this in the case of *Miastor* in midsummer. Moisture and moderately cool weather appear to be especially favorable. With these conditions we are inclined to believe that pedogenesis may continue indefinitely, since we have kept larvæ healthy and multiplying for nearly six months with nothing more elaborate than a moist piece of decaying wood clamped lightly to an ordinary microscopic slide. A larval generation appears to occupy about 3 to $3\frac{1}{2}$ weeks, though it is evident that much depends upon moisture, food and temperature. We were fortunate in the case of two larvæ to witness the development of the egg in the ovary, its gradual separation therefrom by fission and the growth to an individual nearly ready to escape from the mother larva. This entire process occupied about three weeks. The development of the embryo is at the expense of the mother, the young absorbing their nourishment from her. Pulsations in the mother larva continue so long as a fragment of the dorsal vessel remains; in one specimen observed the dorsal vessel of the mother larva was ruptured in the vicinity of the sixth body segment and the free anterior portion continued violent pulsations and irregular wriggings till the next day, at which time the movements were much slower and by the following day had disappeared entirely.

Reproduction by pedogenesis continues in

the spring till just before the final changes to the adult, the larval colonies displaying a marked tendency to arrange themselves in groups and occasionally form rather striking combinations. This occurs, even in the case of colonies established under artificial conditions. At this season at least there is a marked tendency toward uniformity in the production of larval generations, a considerable proportion of the larva in any one colony containing embryos which may escape at about the same time and migrate to another location before establishing themselves. This removal from the exuviae of an earlier generation clearly indicates a phytophagic habit and is presumably of value in avoiding natural enemies. In early May, 1911, embryos escaped in large numbers from mother larvæ, established a colony and in a few days showed a well-developed breastbone. The transformation to the prepupa, characterized by a marked swelling and transparent condition of the anterior body segments of the larva, occurred shortly, they remained in this condition two to three days and then changed to the pupa, a stage lasting about six days. These small midges appeared in enormous numbers in our breeding jars during the late morning hours, namely, from about 9 A.M. until noon, the midges swarming over the sides of the jar and behaving much like minute ants. There is comparatively little tendency to take wing. This may continue for several days and the midges may appear in smaller numbers for a period of several weeks. Larvæ collected in the Adirondacks did not produce midges till in early August. There was a marked preponderance of one sex in rearings from a breeding jar one day, followed by an approximate reversal subsequently. This was not sufficiently marked so that we felt justified in attempting to deduce any general rule. The abdomen of the female contains four to six large eggs, each nearly as long as the abdomen. They appear to be well developed and are probably deposited shortly after the appearance of the midges and the pedogenetic generations commenced wherever conditions are favorable.

Oligarces behaves somewhat differently. A number of larvæ, probably mostly mother larvæ, containing embryos were found in elm bark March 18, 1911. This material was kept in a warm room, and a week later the interior of the jars literally swarmed with thousands of active, whitish maggots with here and there a yellowish or yellowish-transparent one. Many of these perished upon the walls of the jar, and even those confined between a piece of glass and decaying elm bark soon succumbed. In spite of this a pupa was found April 19 and adults obtained about a week later. These small, white larvæ mentioned above differed from typical *Miastor* larvæ and some, at least, evidently established themselves in the crevices of the bark, transforming to pupæ, and these in turn worked out to the free surface a day or so before the disclosure of the imago. These pupæ appeared to move more readily than those of *Miastor*, and in several instances were observed standing upon the moist surface of the bark, supported only by the somewhat mucilaginous posterior extremity.

Natural Enemies.—Both *Miastor* and *Oligarces* larvæ are subject to attack by several predaceous Dipterous larvæ occurring in similar situations. The pinkish larvæ of *Lestodiplosis*, resembling in a general way those of *Miastor* except for a difference in color and more slender structure, may be seen here and there among their prey, and in the case of populous clusters of white *Miastor* larvæ, may give an ornamental touch to the colony. *Itonida pugionis* Felt may also prey on *Miastor*. Two larger predaceous maggots, those of *Lonchæa polita* Loew and a species of *Medeterus* are commonly found in the vicinity of *Miastor* colonies, and it not infrequently happens that they are the only available evidence of the earlier occurrence of *Miastor*. The larvæ of these two latter are voracious forms and are undoubtedly responsible for the speedy destruction of many *Miastor* colonies. The finding of these predaceous larvæ may serve as a guide to the searcher for *Miastor* and suggests investigating the more inaccessible portions of the bark for colonies which may have escaped the predaceous maggots.

E. P. FELT

SPURRED FLOWERS IN CALCEOLARIA

THE genus *Calceolaria*, often popularly called slipperwort, belongs to the Scrophulariaceæ. It may be divided into two sections; first, the herbaceous kind, the one usually employed by florists in this country; second, the shrubby and bedding kinds.

The herbaceous kinds are grown from seeds. When well grown they are very ornamental and serve to decorate the greenhouse in spring, when other plants are through blooming.

The shrubby kinds are serviceable to some extent for indoor decoration. They are extensively grown in Britain for bedding purposes. Owing to the American summers being so hot, they are unsuited for bedding purposes here. They are mostly raised from cuttings.

A little more than a year ago some crossing experiments were conducted by a student in one of the regular undergraduate courses, No. 6, in the department of botany. This course was in charge of Professor Geo. F. Atkinson and Mr. Robert Shore, the head gardener of the department. The student, Miss Margaret C. Graham, performed the experiments under the supervision of Mr. Shore. Since, in public lectures, several unauthorized references have been made to these spurred calceolarias, it seems desirable to place on record the principal facts in connection with the experiments, and to state that the work is still in progress by Professor Atkinson and Mr. Shore.

A shrubby plant was crossed with a herbaceous one. This gave plants of a stronger growth, more profuse bloomers, more compact and more ornamental. Some of these varieties can be propagated from cuttings. These hybrids have been recrossed and the offspring have produced an interesting variety in habit of plants and variation of flowers. Some of the varieties have a number of spurred flowers, one or two spurs on the labelum. These spurred varieties have been cross pollinated and self pollinated, and varieties raised from these seeds have produced several spurred flowers.

THE PRIMARY CONCEPTS OF PHYSICS¹

THE subject of the present address is one that does not often appear on a scientific program. Physicists are so busy in enlarging the structure of knowledge that few of them concern themselves with the consideration of the fundamental concepts of the science. Yet it is plainly true that if those fundamental or primary concepts are not clearly apprehended, or if there is doubt as to what they are, the whole structure of the science rests on an insecure basis. I propose to examine certain questions concerning these primary concepts, about which there has been and is much unsettled opinion. The discussion necessarily rests upon my own beliefs about them. In the nature of the case each man can speak positively about them for himself only. It would be very improper to dogmatize, and I shall accordingly have to crave your pardon for a frequent expression of my own opinion, believing it less objectionable to be egotistic than to be dogmatic.

The first question which I shall consider is that raised by the advocates of the dynamical definition of force, as to the order in which the concepts of force and mass come in thought when one is constructing the science of mechanics, or in other words, whether force or mass is the primary concept. It will be of service in the discussion if we consider briefly the way in which some of the great builders of the science of mechanics used these concepts.

¹ Presidential address delivered before the American Physical Society and Section B of the American Association for the Advancement of Science, at Washington, D. C., December 28, 1911.

There is no need of presenting the views of Archimedes or of Stevinus, whose work was exclusively in statics and who used the concept of force given us by our muscular or motor sense, and measured forces by weights. The views of Galileo, however, are interesting as showing how far one can go in dynamics without using the concept of mass.

Galileo examined the problem of the motion of a body acted on by a constant force. The only constant force of which he could dispose was the weight of a body, or a component of its weight, and he accordingly was limited in his studies to the examination of the laws of falling bodies. Owing to the relation of proportionality between the weight of a body and its mass, this limitation in a way simplified the problem, while at the same time it made it more difficult to develop a complete doctrine of force and motion. By the famous experiment at the Leaning Tower Galileo satisfied himself that he could study any falling body as a type, and that the conclusions which he would reach from that study would apply to all. His attention was therefore directed almost wholly to the consideration of the motion of the falling body, while the question of the relation between the motion and the weight of the body was disregarded. The result of this was that he developed the laws of linear motion with constant acceleration, and numerous consequences of those laws, chiefly relating to motion down inclined planes, with really wonderful completeness, and was led in the course of his thought to a full appreciation and statement of the principle of inertia, while yet he did not, in this part of his work, attain to any useful conception of the relation of force to mass. He makes it clear that the conception of force which is sufficient for his purposes is that with which he was

familiar from his study of statics. He says, in speaking about the "tendency" of a body to fall down inclined planes of the same height, that "It is clear that the tendency of a body to fall is as great as the resistance or the least force which suffices to prevent its falling and to keep the body at rest." In fact Galileo thought of the weight of a body, with which he was familiar from common experience, as a force which moved the body, and assuming that the weight was unchanged during motion his experiments demonstrated what kind of motion such a constant force will set up and maintain.

In the very interesting discussion which Galileo gives of the forces exerted by the collision of one body against another, he approaches nearer than in other parts of his discourse to an appreciation of mass as a characteristic of a moving body. He speaks in one place of the falling body being a composite of weight and velocity, and his discussion of the impulse applied by such a falling body to another on which it falls shows that he was very near the concept of momentum; but there is no real precision in his statements.

We now turn to Newton to get the full doctrine of the relations of force and motion. It will be clear to any one who examines the introductory parts of the "*Principia*," that Newton did not undertake in that book to present a systematic treatise on dynamics. He merely blocks out a rough set of definitions and postulates, in a very uneritical way, which are sufficient to enable him to go on as promptly as possible to the real task which was before him. A striking instance of this uneritical attitude of mind is found in Definition I., in which he says, "Quantity of matter is its measure derived from its density and volume jointly." This quantity of matter thus defined he names

mass. Since we can only define density in terms of the concept of mass, it is surely uncritical to define mass in terms of density. In fact Newton on a later page uses the true definition when he says that bodies are of the same density if their *vires inertiae* (that is, their masses) are proportional to their volumes.

The same sort of uncritical treatment appears in his presentation of the various types of force. He mentions first the *vis insita*, which he defines as the power of resisting, by which a body persists in its state of rest or of uniform motion. He says it differs in no respect, except in the way of conceiving of it, from the inertia of a mass.

Then comes *vis impressa*, the action (*actio*) exerted on a body to change its state of rest or of uniform motion. This is force in our ordinary sense. Newton says that it arises from a blow, from pressures or from centripetal force.

Vis centripeta is the force by which bodies are drawn or impelled from all directions toward any point as a center, or tend toward it in any way whatever. The force of gravitation and magnetic force are examples of this centripetal force. So also is the force by which a sling draws a stone in it toward the hand, which force Newton explains as arising from the stretching of the cord of the sling.

Newton then goes on to define the various measures or modes of giving quantitative expressions for centripetal forces. He first describes the *vis centripetæ quantitas absoluta* as the measure of it as greater or less by comparison with the efficiency of the cause which transmits it from the center through the surrounding region. Thus the magnetic force is greater in one magnet than in another, either because of the greater mass of the one or of the intensity of its power.

The *vis centripetæ quantitas acceleratrix* is the measure of it as proportional to the velocity which it generates in a given time. Thus the power (*virtus*) of a magnet is greater at lesser distances, and less at greater distances; gravitating force is greater in valleys, less on mountain peaks, and less still at greater distances from the earth. At equal distances, he says, this gravitating *vis acceleratrix* is the same everywhere, because all falling bodies are equally accelerated.

The *vis centripetæ quantitas motrix* is the measure of it as proportional to the momentum which it generates in a given time. This quantity is the center-seeking or tendency to the center of the whole body, and (as Newton says, with an evident appreciation that he is limiting the generality of his conception) is the weight of the body. It is always known by the force opposite to it, and equal to it, by which the fall of the body can be prevented.

Newton calls these quantities of force of the various sorts described by the shorter terms motive, accelerative and absolute forces, that is, he substitutes the general terms for the measured quantities of the forces which can be conceived only in those general terms. With this understanding he states that the *vis acceleratrix* is to the *vis motrix* as velocity is to momentum; for the quantity of motion (*momentum*) arises from the velocity and quantity of matter, and the *vis motrix* arises from the *vis acceleratrix* and the quantity of matter. For the sum of the actions of the *vis acceleratrix* upon the several particles of a body is the *vis motrix* of the whole body. Newton relates the *vis motrix* to a body as a striving of the whole body towards the center, made up of the striving of all its parts; the *vis acceleratrix* to the position of the body, as a certain efficiency, diffused from

the center through all places around it, for moving bodies which are in those places. The *vis acceleratrix* as thus described reminds us of the conception of the strength of a field of force.

This analysis of the concept of force surely does not promote a clear apprehension of it. The only one of the distinctions which have been made which seems to be worth retaining is that between the *vis impressa*, or action, and the *vis motrix impressa*, the one being force in its general or conceptual sense, the other the same force when given a measure or value. This distinction was clearly in Newton's mind and appears in the enunciation of the Laws of Motion. In the First Law the departure of a body from its state of rest or of uniform motion is ascribed to the *vis impressa*; that is, to force in general, without any specification as to its measure or even any declaration that it can be measured. In the Second Law the change of momentum is said to be proportional to the *vis motrix impressa*; that is, to force that is measured so that a proportionality to something else can be predicated of it. As has already been stated, Newton declared of this *vis motrix* in the special case of gravitation that it is known, or measured, by the force opposite to it and equal to it, by which the fall of the body, or, in the general case, the motion of the body, can be prevented. In the Third Law the force is called *actio*. This is the alternative word used in the definition of the *vis impressa*, as an equivalent for force in its general sense. The word in this sense is consistently used in the enunciation of the Third Law, in which forces are not considered as measured, but merely as compared by the condition of equality. From the examples of action and reaction which Newton gives (the finger pressed against a stone; the horse drawing a stone by a rope and drawn

back equally toward the stone, because of the stretching of the rope and its exertion of equal forces at its two ends) it is plain that Newton conceived of forces in the way which is familiar to all of us, as the pushes and pulls which can be perceived by our motor sense, and as the causes of motions. He goes on to say that by these *actions* there are caused equal changes, not of velocity, but of momentum, so that the changes of velocity are inversely as the bodies (*corporibus*). In this way, without measuring forces, there is introduced the method of comparing masses.

It is difficult to perceive in these many definitions and declarations exactly what Newton's conception was of force, of the unit in which it is measured and of its relation to mass. After careful consideration of all that I can find in the "Principia" bearing on the question I am convinced that Newton viewed the concept of force as a primary one, or one directly given by intuition, and that he thought of the motions of bodies caused by these forces as connected quantitatively with them by the experimental relation embodied in the Second Law. Since Newton does not use a system of units, and states most of his laws and theorems in terms of proportions, the priority of force to mass, in the order of their apprehension, is not clearly presented.

In the matter of measuring a force he clearly asserts that a *vis motrix* is measured by the force which will counteract it and keep the body to which it is applied at rest, and the force thus used can hardly be other than a force measured statically; but his frequent insistence on the measure of *vis motrix* by the momentum which it causes shows that he had a conception also of the dynamical measure of force. He further supplies the measurement of mass as a fundamental quantity which is needed

to establish the dynamical measure of force by calling attention to the possibility of comparing masses by means of the velocities given them when acted upon by equal forces.

Lagrange in the "Mécanique Analytique" gives the most explicit expression to the definition of force in general which is the bugbear of so many thinkers, and which yet, after all, is the real expression of our belief about force, when he says:

We understand by force the cause, whatever it may be, which impresses or tends to impress a motion on a body to which we suppose it applied.

He goes on to say:

It should be measured by the quantity of motion impressed or ready to be impressed. In the condition of equilibrium, the force produces no actual effect; it produces only a simple tendency to motion; but it should be measured by the effect which it would produce if it were not restrained from acting.

Lagrange repeats this definition of the measure of force in the introduction to his "Dynamics," when he says that the product of the mass and the accelerating force (Newton's *vis acceleratrix*) or the acceleration, expresses the motive force (Newton's *vis motrix*). I can not find that Lagrange gives any definition of mass. From a statement in his treatment of centers of gravity it would seem that he considered the mass to be determined by its weight. He seems to endeavor to measure force in the purely dynamical way, without going into the matter as fully as he should for a complete elucidation of it.

Thomson and Tait say flatly that force is a direct object of sense, and define it as any cause which tends to alter a body's natural state of rest, or of uniform motion in a straight line. They assert that the measure of force is the quantity of motion which it produces per unit of time. They give no other definition of mass than the one given by Newton.

From the account which has been given of the views held or expressed by some of the great leaders of thought in matters of dynamics it is clear that very indefinite notions existed in their minds with respect not only to the proper definition of force, but even with respect to the proper measure of force, which is fundamental and necessary in the development of dynamics. The acute and valuable criticism by Mach of this fundamental notion is so colored in its expression by Mach's favorite principle of economy that it is not altogether satisfactory, and I accordingly shall attempt to present what seems to me the proper order of thought on this matter. Similar statements have been many times made, but there is still no general consent in the minds of physicists as to the statement which should be acceptable to every one.

There is no doubt that the dynamical *measure* of force is the correct one to use in building up a system of units. The point of difference on which dispute arises is the order of precedence of the two concepts force and mass in the establishment of this definition. It is not uncommon to have force defined as the product of mass by acceleration, or of mass by the acceleration which the mass would have if it were free to move. In this definition mass is the primary concept. Now, as I view the question, force is the primary concept, a direct object of sense, and we know it to be a cause of motion, or of the distortion of a body to which it is applied and which counteracts it when the distortion has reached a certain limit. In particular we know it as counteracting, or as being counteracted by, the weight of a body. This conception of force is adequate for the development of statics, in which we treat the principles of statics as statements of laws which are derived from experiment and confirmed by the proof that they are

mutually consistent. Galileo's experiments on falling bodies are then the direct experimental proof in a limited case of the proportionality between the force which acts on a body, measured at any one place by a weight, and the acceleration imparted to the body. Newton's Second Law is a statement of Galileo's discovery, with this addition, that the acceleration imparted by a force is not the same for all bodies, but depends upon a certain characteristic of the body. This characteristic, the mass of the body, first calls for recognition at this point. In the view I have taken the mass is the factor of proportion between the force which acts on a body and the acceleration which it imparts to the body. Since we can measure forces by comparison with a standard force, we can also measure masses by the aid of properly instituted experiments. Whether we measure masses in this way or not, and it turns out to be not a satisfactory way to do it, we at least get from this relation between force, of which we have a concept, and motion, of which we have a concept, an adequate working concept of mass. Force is the primary concept and mass is a derived concept.

Now owing to the permanency of masses of matter it is convenient to construct our system of units with a mass as one of the fundamental units. We are able to do this and to compare one mass with another chosen as standard, without going through the operation of measuring forces, by utilizing the principle embodied in Newton's Third Law. This law asserts that bodies which interact, that is, which exert forces on each other, exert equal forces, and thus, if the bodies are free to move, their acceleration will be inversely as their masses. By observation of the accelerations of two mutually interacting bodies we may thus compare their masses, and so

construct a set or scale of masses, and use these masses and their accelerations to measure forces. Thus while the concept of force is primary in the order of thought, we may make the unit of mass fundamental in the development of a system of units.

The point upon which I wish to insist is that both reason and the history of mechanics show that the foundation of the science is the purely intuitional concept of force which is shared by every intelligent being, and that this intuitional concept is not only accurate so far as it goes, but adequate to serve as the foundation of a great science. No use of the concept of force in the theories of physics has ever violated in any particular this original and intuitional concept of it. Even the brilliant endeavor of Hertz to found all the principles of dynamics upon the three concepts of time, space and mass can not escape the criticism that the concept of mass is meaningless to us unless it is given to us by our experience of the inertia of matter when we exert force upon it. Once that concept is attained it may be used, as Hertz so beautifully used it, in the logical upbuilding of a system of dynamics. Perhaps my contention will be made clearer if we consider briefly the question whether it would be possible for us to construct our present system of dynamics if we were disembodied spirits, gifted with the means of observing spaces, times and colors, but without the sensation of force. We could see colored volumes, sometimes moving with constant velocity, sometimes with varying velocity, and we could ascribe the changing velocity to the action of a force. We further could connect the force with the moving volume by setting it equal to the acceleration multiplied by some factor which we might name the mass. This equation would contain two unknown and

unmeasured quantities, and would mean nothing unless we could go further. Now the advocates of the purely dynamical definition of the concept of force say that we can go further, by observing the mutual accelerations of two bodies and using these to obtain the ratio of their masses. If this can be done the matter is settled. But could it be done by the disembodied spirit? In our use of the mutual accelerations of two bodies to get their masses we must explicitly state that the bodies are arranged so as to interact (that is, to exert force on each other), and unless that condition is established the mutual accelerations of two bodies, however often repeated, can tell us nothing about their masses. A man at a station might observe two trains leaving the station in opposite directions with the same accelerations every day for ten years, and yet he could not compare their masses by any such observations. Eyes and mind only will not do it. To get the measure of mass we must start with the intuitional knowledge of force, and use it in the experiments by which we first define and then measure mass.

I now come to a much more difficult part of my subject, the consideration of the other primary concepts of space and time. Not many years ago we should have been willing to pass them over with a mere mention, admitting the impossibility of giving a definition or even an intelligible description of either of them, admitting the impossibility of determining an absolute or fixed point in space, or an absolute instant of time, but still asserting that we knew something about them both of which we were sure. At present we are driven by the development of the principle of relativity to examine anew the foundations of our thought in respect to these two primary concepts.

I suppose that the old ideas about space and time that have been of service to physicists since the beginning of the science are summed up as well as anywhere in Newton's words:

Absolute and real time, the time of the mathematician, flows on equably, having no relation in itself or its nature to any external object. It is also called duration. Relative, apparent time, the time of common life, is an external measure of any duration cognized by the senses, by means of motion. It is commonly used in place of real time.

Absolute space, having no relation in its nature to any external object, always remains alike everywhere and immovable. Relative space is the measure of this space, or any movable dimension, recognized by our senses as limited by its situation with respect to bodies. This is commonly thought of as equivalent to absolute space.

These definitions have been often justly criticized for the emphasis laid on the unfruitful ideas of absolute time and space. Perhaps the criticism has fallen rather upon Newton's subsequent expansion of his thought on these ideas. But do they not contain in the first place the conceptions of time and space which have been uniquely useful up to this time in physics, and in the second place, do they not contain what each one of us really thinks about time and space when he makes an honest examination of his knowledge? The essential feature of both these descriptions for our present purpose is Newton's declaration, both as to time and space, considered as species and not as magnitudes, that they are in themselves and in their nature without relation to any external object. It is this statement which is contradicted by some of the enunciations of the principle of relativity.

It is not necessary for me to give an account of the genesis of the principle of relativity. It may fairly be said to be based on the necessity of explaining the negative result of the famous experiment of Michelson and Morley, and on the con-

venience of being able to apply Maxwell's equations of the electromagnetic field without change of form to a system referred to moving axes. It is not needed to explain many of the remarkable results obtained by Fizeau, by Mascart and by Brace, in the field of experimental optics, which to a first inspection seem to show that the earth and the medium around it through which light passes are relatively at rest, but which a closer study by Lorentz and others shows may be compatible with a reasonable theory of the structure of matter and the hypothesis that the luminiferous medium is at rest. It is also not needed to explain the dependence of the path of an electron in a field of crossed electric and magnetic forces upon its velocity, as exhibited in the beautiful experiments of Kauffmann and of Bucherer, for other theories in which the principle is not used lead to expressions for the path which, for the present at least, are in as good accord with observation as those which are deduced by the aid of the principle of relativity.

There are two ways of presenting the principle of relativity. In the first way the principle is stated as a direct inductive conclusion from the experiment of Michelson and Morley, and asserts that so far as a conclusion can be drawn from that experiment and the others which have been tried to test the matter, there is no way by which the relative motion of the earth and the luminiferous medium can be determined from observations made on the passage of light when the source of light and the observer are moving with the earth. As thus presented the principle holds out as the object of future study the construction of a suitable theory of the structure of matter and of the luminiferous medium to account for this fundamental experiment as well as for all other known truths in the domains of light and electricity. If

this theory is expressed in terms of the Lorentz transformation, and thus shows a dependence of the measure of time and the measure of length upon the velocity of the system in which the observer is placed, it will further be the object of inquiry to construct a theory of the relations between the material of the system and the luminiferous medium which will account for the change in the units of length and in the motions of bodies by which the unit of time is determined. When I say to account for, I mean to describe in terms of force, time and space, as we conceive those notions in our every-day experience, and as we use them in our ordinary physical work, so that the description when apprehended will be reduced to the lowest terms in which our thought about the universe can be expressed. Such a description is, as I view it, a real explanation, and surely it is not yet time to say that such an explanation is impossible.

The other way of presenting the principle of relativity consists in laying down as a fundamental postulate a general proposition expressing the hopelessness of any attempt to settle the question raised by the experiment of Michelson and Morley by any theory of the structure of the universe. This postulate sometimes assumes a formidable aspect, and involves more than the mere postulate of relativity. Thus Laue says:

The principle of relativity asserts that from the totality of natural phenomena we may, with continually increasing approximation, determine a system of reference, x, y, z, t , in which the laws of nature hold in a definite and mathematically simple form. This system of reference is by no means uniquely determined by the phenomena. There is rather a triple infinity of equally admissible systems, which move relatively to one another with uniform velocities.

The feature of this enunciation of the principle to which I referred as an addi-

tion to the principle is the expressed condition that in the system of reference the laws of nature hold in a definite and mathematically simple form. There is no warrant in the past history of physics for the adoption of such a postulate as that. Surely the history of the discovery of the so-called secondary laws of physics, such as Boyle's law, the laws of friction, the laws of polarization and of absorption of light, the laws of magnetization, and many others, will bear out the statement that in very many cases the first enunciation of the law is in a definite and mathematically simple form, and that further knowledge shows that this form is only a first approximation to the truth. Even in the case of such laws as the law of gravitation, or of electrical attraction and repulsion from which we have not yet detected any deviation, does any one dare to say that they are universally true for all bodies and at all distances? Can we even feel sure that Maxwell's electromagnetic equations hold true with absolute exactness? They need supplementing when they are applied to material bodies. Can we be sure that they hold without modification, in rapidly moving bodies, or at extremely minute distances in free space. Or, from another point of view, admitting that the object of physical study is to reduce the description of natural phenomena to a set of simple laws, have we a right to assume that, in our analysis of the structure of matter and of the luminiferous medium, we have as yet reached the ultimate model in which such simple laws will be operative? The answer to this question must be a negative one. Yet it is surely true that if it were not for this demand of simplicity, immediately attainable and at present expressed in the electromagnetic equations, the chief incentive to the development of the theory of relativity would be wanting.

But this is not the heart of the matter. With the principle of relativity as a basal postulate, not expressing our present inability, but rather the hopelessness of any attempt to obtain ability, a complete description has been given of the phenomena now known to physicists, at least in the domains of mechanics, light and electricity. The difficulty which I find in accepting the principle, with the universality that is predicated of it, is that it does so much more than this.

The theories of J. J. Thomson and of Lorentz made physicists familiar with the notion of electrical mass, exhibited by the variability of the mass of a moving charged body, or by the apparent variable inertia of a moving charge expressed as a function of its velocity, and further with the notion that as the velocity of the charge approaches the velocity of light the magnitude of the electrical mass approaches infinity, so that the velocity of an electrical charge, of an electron, and therefore presumably of matter, if it is entirely electrical in its structure, can never surpass the velocity of light. In these theories this remarkable conclusion was explained by the interaction between the moving charge and the ether. In the theory of relativity the same conclusion is reached as the consequence of a purely kinematical theorem, giving the rule for the addition of velocities, and not only does it hold for real moving charges, but for any action whatever which is conceivably transmitted through space. In particular this finite velocity of transmission must be ascribed to gravitational action. Now the Newtonian theory of gravitation assumes a practically infinite velocity of transmission of gravitational action, and astronomical observations have never given any warrant for the belief that its velocity of transmission is even of the order of mag-

nitude of the velocity of light. The attempt has been made to reconcile the theory of relativity with the observed motions of the planets by the adoption of an arbitrarily chosen term in the formula for the force on a planet to represent what is equivalent to a counteracting force to annul the tangential acceleration which would arise from the finite rate of transmission of gravitational force. This is manifestly an artifice and not an explanation. If the principle of relativity is of universal application, it should not need the introduction of such an artifice to help it out in the solution of one of the classical problems of physics.

Further, the principle of relativity in this metaphysical form professes to be able to abandon the hypothesis of an ether. All the necessary descriptions of the crucial experiments in optics and electricity by which the theories of the universe are now being tested can be given without the use of that hypothesis. Indeed the principle asserts our inability even to determine any one frame of reference that can be distinguished from another, or, what means the same thing, to detect any relative motion of the earth and the ether, and so to ascribe to the ether any sort of motion; from which it is concluded that the philosophical course is to abandon the concept of the ether altogether. This question will be amply and ably discussed this morning, but I may venture to say that in my opinion the abandonment of the hypothesis of an ether at the present time is a great and serious retrograde step in the development of speculative physics. The principle of relativity accounts for the negative result of the experiment of Michelson and Morley, but without an ether how do we account for the interference phenomena which made that experiment possible? There are only two ways yet thought of to account

for the passage of light through space. Are the supporters of the theory of relativity going to return to the corpuscles of Newton? Are they willing to explain the colors of thin plates by invoking "the fits of easy reflection and of easy transmission?" Are they satisfied to say about diffraction that the corpuscles near an obstacle "move backwards and forwards with a motion like that of an eel"? How are they going to explain the plain facts of optics? Presumably they are postponing this necessary business until the consequences of the principle of relativity have been worked out. Perhaps there is some other conceivable mode of connection between bodies, by means of which periodic disturbances can be transmitted. We may imagine a sort of tentacular ether stretching like strings from electron to electron, serving as physical lines of force, and transmitting waves as a vibrating string does. Such a luminiferous medium would not meet the postulate of simplicity, but it conceivably might work. But whatever the properties of the medium may be, there is choice only between corpuscles and a medium, and I submit that it is incumbent upon the advocates of the new views to propose and develop an explanation of the transmission of light and of the phenomena which have been interpreted for so long as demonstrating its periodicity. Otherwise they are asking us to abandon what has furnished a sound basis for the interpretation of phenomena and for constructive work in order to preserve the universality of a metaphysical postulate.

The electromagnetic equations, too, the retention of which in their present simple form is the *sine qua non* of the promoters of the principle of relativity, were not only developed by the conscious use of the hypothesis of a medium in which the electric and magnetic forces exist, but can be inter-

preted intelligibly only in terms of some such medium. The abandonment of this hypothesis reminds one of Baron Münchhausen's feat performed while he was making his escape from prison. Since your historical reading may not have extended to the autobiography of this famous man, I may be permitted to relate that the Baron was letting himself down from the windows of a high tower by a rope, and when he reached the end of it he found that he still had a long distance to go. The last part of the descent was particularly difficult, so to get rope enough he ingeniously spliced on an additional piece, which he obtained by cutting off the part above him.

The principle of relativity in its metaphysical form ignores the accelerations of bodies. It is true that the experimental results to which the principle has been applied with such success are such that the study of acceleration in terms of the theory of relativity has not become necessary. But is it not reasonable to suppose that when suitable experiments have been invented and tried to test the effect of the acceleration of a system on the progress of light in it, it may be found that an effect can be detected? Some effect may be detected, for example, due to the rotation of a body. I have never been able to perceive any sound objection to Newton's assertion that we have evidence of absolute rotation by the observation of centrifugal force, and if a fixed direction of an axis and an absolute velocity of rotation can be determined in a mechanical system when accelerations are taken into consideration, why should the principle of relativity be treated as having universal validity?

But, after all, these questions raised by the development of the principle of relativity are of secondary importance. The central question is whether or not this prin-

ciple can ever furnish a satisfactory explanation of natural phenomena. The formulas derived from it are evidently merely descriptive. This may be said with truth about all the formulas in which the general theories of physics have been embodied. Kirchhoff designates, as the task of the science of mechanics, the description of the motions which occur in nature completely and in the simplest possible way. This assertion that the task of the theoretical physicist is done when he has reduced the phenomena with which he is dealing to a set of formulas, or, as we may say, when he has constructed an ideal model which will reproduce the phenomena, is one to which we would all assent in general. At the same time most of us would reserve the right to criticize each model thus presented, and to give to one or the other a preference based on considerations which are not necessarily limited to the simplicity of the model or to the completeness with which it reproduces the phenomena. Surely an additional test of the value of the model will be the intelligibility of the elements of which it is composed.

This last test has been generally met in the models which have been proposed as descriptions of natural phenomena. We can understand from what we see and feel what is meant by the motions of elastic spheres, and the model which uses them to represent the behavior of a gas is not only competent to reproduce the behavior of a gas, but is intelligible in the elements of which it is composed. The model of the elastic solid ether, incomplete and objectionable as it became when the subject of optics was enlarged and developed, was intelligible in its elements. The model of electromagnetic operations embodied in Maxwell's formulas is also one which is thus intelligible in its elements. When I say this I do not mean that we know all

about electric and magnetic forces, but I mean that we do know enough about such forces to have a clear notion of their variation in space and their variation in time.

This feature of the ideal model or description seems to me to be necessary in order to make the model acceptable as the ultimate or last attainable explanation of phenomena. The elements of which the model is constructed must be of types which are immediately perceived by the senses and which are accepted by everybody as the ultimate data of consciousness. It is only out of such elements that an explanation, in distinction from a mere barren set of formulas, can be constructed. A description of phenomena in terms of four dimensions in space would be unsatisfactory to me as an explanation, because by no stretch of my imagination can I make myself believe in the reality of a fourth dimension. The description of phenomena in terms of a time which is a function of the velocity of the body on which I reside will be, I fear, equally unsatisfactory to me, because, try I ever so hard, I can not make myself realize that such a time is conceivable.

Tried by this test, I feel that the principle of relativity does not speak the final word in the discussion about the structure of the universe. The formulas which flow from it may be in complete accord with all discovered truth, but they are expressed in terms which themselves are not in harmony with my ultimate notions about space and time. That this is true is so evident that it is generally admitted. Some writers say that we should not let this circumstance disturb us, because Kant has said that time and space are mere forms of perception, a scheme in which we must arrange occurrences so that they may acquire objective significance. I do not altogether understand what Kant meant by this, but I am

sure he did not mean that by the exercise of our wills we can violently eject from our consciousness the notions of space and time which we have in common with the whole race of man, and impose on ourselves other and radically different notions. Planck compares our position before the new notions presented by the theory of relativity to the position of the medieval peoples before the notion of the antipodes. It seems to me that there is no real similarity between the two positions. Many men in the Middle Ages believed that there were no antipodes, but their belief was based on reasons, and so far were they from being unable to conceive of antipodes and to believe in their existence, that there were men who actually maintained their existence, and were pursued therefor as heretics. I do not believe that there is any man now living who can assert with truth that he can conceive a time which is a function of velocity or is willing to go to the stake for the conviction that his "now" is another man's "future" or still another man's "past."

One of the members of this society, recognizing our present inability to conceive of relative time, and conceiving our intuitions of space and time to be the result of heredity operating through many generations of men who lacked the light of relativity, once proposed to me that every one who could get even a glimmer of the notion of relative time should persistently exercise his mind therein and teach it to his students, in the hope that in a few generations the notion would emerge with the force of an intuition. It would not be fair to leave the impression that he was solemnly serious when he made this suggestion. When Matthew Arnold was asked to endure the transliteration of Greek names into English in order that the new forms might become familiar to future scholars,

he answered that he was not willing to spend his days in a wilderness of pedantry that his children might enjoy an orthographical Canaan; and *mutatis mutandis* the same answer may be given in this case. But a more pertinent answer is, to my mind, this, that the attempt to reorganize the perceptions of the human mind in respect to space and time is doomed to failure. "Which of you by taking thought can add one cubit unto his stature?" I believe that these ultimate perceptions are the same for all men now, have been the same for all men in the past, and will be the same for all men in the future. I believe, further, that this is true because the universe has a real existence apart from our perceptions of it, and that through its relations to our minds it imposes upon us certain common elementary notions which are true and shared by everybody.

Therefore, from my point of view, I can not see in the principle of relativity the ultimate solution of the problem of the universe. A solution to be really serviceable must be intelligible to everybody, to the common man as well as to the trained scholar. All previous physical theories have been thus intelligible. Can we venture to believe that the new space and time introduced by the principle of relativity are either thus intelligible now or will become so hereafter? A theory becomes intelligible when it is expressed in terms of the primary concepts of force, space and time, as they are understood by the whole race of man. When a physical law is expressed in terms of those concepts we feel that we have a reason for it, we rest intellectually satisfied on the ultimate basis of immediate knowledge. Have we not a right to ask of those leaders of thought to whom we owe the development of the theory of relativity, that they recognize the limited and partial applicability of that

theory and its inability to describe the universe in intelligible terms, and to exhort them to pursue their brilliant course until they succeed in explaining the principle of relativity by reducing it to a mode of action expressed in terms of the primary concepts of physics?

WILLIAM FRANCIS MAGIE

PRINCETON UNIVERSITY

THE MOVEMENT FOR SCIENTIFIC INTERNATIONALISM AT THE HAGUE

PEDAGOGY lays ever greater emphasis on positive suggestion of the things that are good to do, rather than on negative prohibition of what is undesirable. The peace movement, as one of the biggest educational problems now in hand, is applying this principle in many ways. Everything which makes more evident the common interests of mankind tends toward peace as it awakens the larger loyalties which more and more take the place of primitive Chauvinism. The things which are specifically national are few and the things which are co-extensive with human thought and human effort, many. If a realization of this fact were deep enough and wide enough men would altogether refuse to allow their interest and their public moneys to be diverted from the great common task, the advance of knowledge and its application to human welfare, by the little jealousies between groups which happen to live under different political organizations. The Foundation for the Promotion of Internationalism at The Hague has for its purpose the furthering of those movements for intellectual and social progress which are international in scope, and by so doing it plays an important part in the growth of the spirit of world peace.

It is obvious that, if such ends are to be realized, the efforts made must tend to meet practical needs in various fields of thought and action and not merely express a vague aspiration toward abstract ends. The Foundation for the Promotion of Internationalism has therefore addressed itself to a systematic study of the various movements for inter-

nationalism and the needs which they indicate, the shortcomings of previous efforts and the most profitable lines for future advancement. Two monographs already prepared by Dr. P. H. Eijkman, Director of the Preliminary Office of the Foundation, deal with "*L'Internationalisme Medical*," 1910, and "*L'Internationalisme Scientifique*," 1911, and these volumes furnish a most impressive argument for the "organization of organizations" contemplated by the foundation.

The advantages to be gained by international organization may be best estimated perhaps by considering what national associations have already accomplished within their more limited territory. The services of the American Association for the Advancement of Science, the American Medical Association and the American Public Health Association and the American Chemical Society, for example, have been notable forces in their respective fields. Such organizations serve a twofold purpose. On the one hand, by their meetings and by their publications they serve as a medium of communication between their members, bringing the experience of each to the service of all. On the other hand, they serve as an authoritative medium of communication with the public, furthering as occasion demands a popular knowledge of the subjects with which they deal, and presenting a united influence upon official action to which their sciences are, or should be, related.

The transition from such national societies to international ones has been a natural and inevitable one, and has led to the formation of world organizations and world congresses, in profusion. How numerous such international efforts have been no one probably realized until Dr. Eijkman brought them together (for medicine and for pure science and letters) in the two volumes to which reference has been made. In the second of his books he lists over 600 international organizations and Professor Baskerville in an article on International Congresses in *SCIENCE* for November 11, 1910, catalogues 125 international congresses in science alone. These diverse international societies and congresses have proved of great

importance; but they fall far short of the needs, for a world organization of intellectual effort. For the most part there has been no permanent organization to connect adequately the work of successive congresses and there has nowhere been a due correlation between the work of different groups, drawn together often by some local or temporary need. There is duplication, on the one hand, with unoccupied fields on the other, and while certain congresses have been markedly successful, others have fallen short of reasonable expectation. All these defects must be to some extent inherent in human undertakings; but they could surely be minimized by a central bureau which could correlate the more important lines of intellectual activity and give to each of them a permanent organization.

Such an idea led to the establishment of the Office Centrale des Institutions internationales at Brussels and to the calling together under its auspices, of the *Congres mondial des Associations internationales* in 1910. The field covered by this congress was so wide, however, that it could hardly hope to accomplish very much along specific lines. Every sort of international movement was included in the Brussels program and it is a somewhat large task to organize all at once the whole field of international life. The Foundation for the Promotion of Internationalism at the Hague has wisely determined to address itself rather to the specific problems presented by certain definite branches of science rather than to any all-embracing programs.

The most promising line of advance, as Dr. Eijkman has well shown in his volume on "*L'internationalisme scientifique*," has been marked out by the development of permanent organizations, of international scope, but dealing with related problems and representing naturally cooperative groups. Of these the Association internationale des Academies furnishes the most notable example. Representing as it does twenty-two academies in the leading scientific nations of the world, it occupies an authoritative position in pure science and letters and it has undertaken since its first general meeting in 1901 a series of

practical tasks of the first magnitude, tasks which only a world organization could successfully undertake. Among them may be mentioned the publication of a complete edition of the works of Leibnitz, an encyclopedia of Islam, a critical edition of the Mahabharata, an annual publication of physical and chemical constants, the measurement of an arc of the thirtieth meridian, the organization of a central committee for the study of the brain and the development of the work of the Institut Marey and the laboratories on Mont Rose.

The International Association of Academies still lacks, however, a permanent home and an opportunity for correlating its efforts with those of similar organizations dealing with related work in various branches of applied science and art. This is the dream of the Foundation for the Promotion of Internationalism, a series of such strong international bodies representing the most important fields of intellectual endeavor, all with permanent bureaus at the Hague, and all working together on definitely correlated lines for the organization of human effort.

This is not merely a dream. Two such bureaus are already well under way and a third has just come into existence. The Bureau de la Commission permanente des Congres internationaux de Medecine was established at the 16th International Congress of Medicine at Budapest in 1909. Its functions include the general planning of congresses and the arbitration of disputed points, the designation of place of meeting, standards for membership, official languages, number and scope of sections and number of papers presented, scrutiny of the votes passed by sections, correspondence with other international congresses and societies in order to avoid conflict, the promotion of the study of medical questions requiring international cooperation and the institution of commissions for such purposes. At the Brussels meeting of the International Congress of Pharmacy in 1910, a similar organization was effected in the shape of a Bureau permanent de la Federation internationale de Pharmacie, also with offices at

the Hague. The objects of this international federation are fully and definitely outlined and include the collection and dissemination of data in regard to scientific and practical pharmacy, the promotion of uniformity in educational requirements for pharmacists, the study and dissemination of information in regard to laws relating to pharmacy, the organization of international pharmaceutical congresses, collaboration with other international societies and many more. The third permanent international bureau at the Hague has just been established in the form of a Bureau permanent de l'Institut international de Statistique.

The Foundation for the Promotion of Internationalism, which was an active agent in the creation of these three bureaus, is anxious to continue its admirable work by the development of similar permanent organizations in related fields. Dr. Eijkman, its director, is at present in America with a view to arousing interest in three such undertakings which seem of immediate practical importance. The first of these is a permanent international bureau for pure science and letters which would seem to be a natural development of the International Association of Academies and might properly be undertaken under its auspices. The second is a similar bureau for hygiene (public health would be a far better term, but the word hygiene is probably too firmly entrenched in European parlance to be dislodged). Public health has far outgrown the bounds of medicine, since it includes specialists in engineering, biology, bacteriology, chemistry and statistics, as well as in medical science; and the Permanent Commission of International Medical Congresses at its first meeting in London endorsed the plan for a bureau of hygiene at the Hague. No field of scientific effort has more manifold international relations than public health and it is to be hoped that the International Congress of Hygiene and Demography may take definite steps toward this end at its meeting in Washington next fall. Finally, the Foundation for Internationalism hopes to secure the establishment of a third new bureau

dealing with technology; and the International Congress of Applied Chemistry which meets in Washington and New York in September might well institute a movement toward this end.

These plans for international scientific bureaus at the Hague have the cordial support of the government of the Netherlands which is financing the bureaus so far created and the cooperation of the leading European men of science. The Preliminary World Committee includes in a list of several hundred the names of Arrhenius, v. Babes, Bang, Bertillon, Ehrlich, E. Fischer, Flügge, R. Hertwig, van't Hoff, Landouzy, Leduc, Lockyer, Madsen, Metchnikoff, Oppenheim, Ostwald, Ramsay, Richet, Roux, Rubner, Salomansen, Sanarelli, Schuster, Scott-Sherington and Waldeyer. In the United States he has already secured the adhesion of J. McKeen Cattell, Harvey Cushing, George Dock, E. Dana Durrand, John S. Fulton, George E. Hale, W. G. MacCallum, S. N. D. North, Henry Fairfield Osborn, E. C. Pickering, Ira Remsen, Charles D. Walcott, W. H. Welch and many others.

These efforts deserve the cordial support of American men of science, both for the practical service which the proposed permanent international bureaus would render to their respective sciences and arts and for their beneficent effect upon the movement for peace and for the progressive organization of the world.

C.-E. A. WINSLOW

AMERICAN MUSEUM OF NATURAL HISTORY,
NEW YORK

SCIENTIFIC NOTES AND NEWS

DR. SIMON FLEXNER, director of the Rockefeller Institute for Medical Research, has sailed for Europe to give the Harben lectures before the London Institute of Public Health and the Cameron lecture at Edinburgh University.

ON account of illness Professor Josiah Royce, of Harvard University, has been compelled to give up the course of Bross lectures

on "The Sources of Religious Insight" and has been given leave of absence for the present academic year.

PROFESSOR W. A. NOYES, director of the chemical laboratories of the University of Illinois, has been granted leave of absence to go to Berlin as the representative of the American Chemical Society at the International Conference of Chemical Societies.

THE directors of the Bache Fund of the National Academy of Sciences have voted a grant of \$500 to Professor M. A. Rosanoff, of Clark University, in aid of his research on the dynamics of sugar inversion.

THE Sarah Berliner research fellowship for women has been awarded to Miss Marie Gertrude Rand, of Brooklyn, a doctor of philosophy of Bryn Mawr College, for her work on the psychology of vision.

DR. GUSTAV HELLMANN, director of the Meteorological Bureau in Berlin, has been elected a member of the Berlin Academy of Sciences.

SIR EDWIN RAY LANKESTER has been elected an honorary student of Christ Church, Oxford.

DR. CHARLES CHILTON, professor of biology at Canterbury College, New Zealand, has been granted leave of absence for 1912, and will spend the year in Europe visiting biological laboratories and stations.

PROFESSOR FREDERIC B. LOOMIS, of Amherst College, Waldom Shumway, '11, and Philip L. Turner, '12, members of the Amherst biological expedition to South America, arrived at Amherst last week from Buenos Aires. The party left this country last July and has been occupied in the exploration of practically unknown territory in southern Patagonia. A large collection of fossil remains has been obtained.

PROFESSOR T. A. JAGGAR, JR., of the Massachusetts Institute of Technology, has been granted leave of absence for the remainder of the year that he may perfect the plans for the Volcanic Laboratory at Halemaumau in the Hawaiian Islands. This observatory has been

in the charge of Professor Perret during the past summer.

PROFESSOR F. O. GROVER, head of the department of botany of Oberlin College, devoted a portion of the summer recess to work on Monhegan Island, Maine, where he discovered several unknown plants and extended the known distribution of other species. His most important find was a specimen of *Carex crinita porterei*, which has not been seen by botanists since its discovery at Moosehead Lake in the early seventies.

PROFESSOR ERICH VON DRYGALSKI, of Munieh, leader of the German South Polar Expedition, has been entrusted by the Prussian Academy of Sciences with the continuation of the explorations in China begun by the late Professor Ferd. von Richthoven.

DR. MARCUS BENJAMIN, of the U. S. National Museum, has been appointed by the president to serve on the Assay Commission that meets in Philadelphia on February 14.

UNDER the auspices of the College of Sciences, a series of lectures will be given at the University of Illinois by Professor W. Johannsen, of the University of Copenhagen, on "Modern Problems of Heredity." These lectures will be given from February 26 to March 2, 1912. The first lecture at the University of Illinois will be an introductory one on such topics as "The Primitive Conception of Heredity." "Transmission" of Personal Characters," etc. The second on "The Principle of Pure Lines." The third lecture, "Mendelism." The fourth, "Complications and Exceptions." The fifth, "Mutations." The sixth lecture, "Continuity or Discontinuity in Evolution." From March 4 to 10 a series of five or six lectures will be given, also under the auspices of the College of Science, by Professor W. Kukenthal, of the University of Breslau.

ON January 16 Professor W. Bateson began a course of six lectures at the Royal Institution on "The Study of Genetics."

PROFESSOR V. VOLTERRA, of the University of Rome, is giving a series of lectures at the University of Paris on the extension of the

theory of functions, the integro-differential equations and integral equations, with applications.

THE Moissan memorial lecture before the London Chemical Society will be delivered by Sir William Ramsay, on February 29.

PROFESSOR W. JOHANNSEN, of the University of Copenhagen, gave an address on "Problems of Heredity" before the Minnesota chapter of Sigma Xi on the evening of February 10.

PROFESSOR A. V. BLEININGER, of the University of Illinois, delivered a series of lectures on the theory and technology of clays and other silicates, before the classes in economic geology of the University of Chicago, January 22-27.

DR. W. A. HEIDEL, professor of Greek at Wesleyan University, gave an address on "The Beginnings of Science" before the Middletown (Conn.) Scientific Association on February 13.

EDWARD M. EAST, assistant professor of experimental plant morphology, Bussey Institute, Harvard University, lectured at Trinity College on the evening of February 16 on "Influences of Recent Advances in Biology in the Art of Plant Breeding."

PROFESSOR M. A. ROSANOFF, of Clark University, lectured on February 1 and 2 before the industrial research fellows at the University of Pittsburgh on "The Partial Vapor Pressures of Liquid Mixtures."

MR. HAROLD PARKER, on February 9, delivered a lecture on "Contracts and Specifications" before the graduate students in highway engineering at Columbia University.

THE senior class of the Colorado School of Mines has recently been given addresses by professional men of Denver. Mr. Frank E. Shepard, president of the Denver Engineering Works Co., spoke on "Modern Mill Practice" and on "Modern Mill Plant Design"; Mr. John C. Traylor, of the Traylor Engineering Works, spoke on "Jigging," and Mr. W. H. Trask, consulting engineer for the Cen-

tral Colorado Power Co., spoke on "Modern Hoisting Installations."

PROFESSOR W. E. CASTLE has returned from the expedition which he recently made to Peru under the auspices of the Carnegie Institution of Washington, having succeeded in obtaining from two different localities, one in southern and one in central Peru, wild cavies supposed to be closely related to the domesticated guinea-pig. These will be used in breeding experiments at the Bussey Institution. The event is of interest to zoologists as being probably the first introduction of living individuals of the ancestral guinea-pig into North America or Europe. This fact is the more surprising when it is remembered how extensive and important is the use of the guinea-pig in biological investigation and the public health service. Not only is the wild guinea-pig unrepresented in any zoological garden, but even our greatest museums possess scarcely a specimen of it. The transportation of the animals for several thousand miles through a variety of climatic conditions involved some difficulties, which, however, were all successfully met. Small round market-baskets lined with wire netting served as cages, and cucumbers and watermelons for food during transportation through the tropics. Some domesticated guinea-pigs were also obtained from Peruvian natives for comparison with the ordinary European sorts, which probably reached Europe from South America centuries ago.

A COMPREHENSIVE project for research on the Cactaceae has been organized by the department of botanical research of the Carnegie Institution of Washington. Dr. J. N. Rose, of the U. S. National Museum, who has explored much of the region inhabited by these plants in Mexico and the United States and published extensively on the family, has been appointed research associate. He has been granted a furlough from the museum, which also furnishes working quarters and facilities for handling the living collections. Dr. N. L. Britton, who began organizing a collection of cacti in the New York Botanical Garden

in 1900, and has since made extensive studies of the group, has also been appointed research associate, without salary. By the action of the scientific directors of the garden he will be given some respite from other duties to enable him to participate in this work. The garden also contributes its extensive collections, and some of its explorational effort to the project. Dr. D. S. Johnson, of Johns Hopkins University, will spend several in 1911 on the morphology and physiology of the fruits of the group, and Professor J. G. Brown, of the University of Arizona, will continue his studies on the general morphology of *Opuntia* and *Carnegiea* begun while acting as assistant at the Desert Laboratory. Other contributions will be made by the members of the staff and cooperators of the Desert Laboratory.

THE fifth annual meeting of the Illinois Academy of Science will be held at Bloomington, Illinois, Friday and Saturday, February 23 and 24, under the auspices of the McLean County Academy of Science. The sessions will begin at 2:00 p.m. on Friday and will continue through Saturday afternoon. A symposium on Conservation will be given at the Saturday morning session, the speakers and their subjects being as follows:

"Conservation of Our Coal and Oil," F. W. DeWolf, director, Illinois State Geological Survey.

"Water Pollution," Edwin O. Jordan, professor of bacteriology, University of Chicago.

"Conservation Ideals in the Improvement of Plants and Animals," Herbert J. Webber, professor of plant breeding, Cornell University College of Agriculture.

"Conservation of Our Forests," Henry C. Cowles, associate professor of ecology, University of Chicago.

"Conservation of Our Fauna," S. A. Forbes, director, Illinois State Laboratory of Natural History.

"Conservation of the Human Race," J. N. Hurty, secretary, Indiana State Board of Health.

A banquet will be given at the Illinois Hotel on Friday evening, after which the president, Professor W. A. Noyes, will address the academy, the subject being "The Electron

Theory." Many papers of scientific and educational interest will be presented during the sessions.

A COURSE of six lectures under the auspices of the Chicago Nature Study Club is being given at the Academy of Science, Lincoln Park, on Saturday afternoons at 1:30 as follows:

February 10—"Schoolroom Aquaria," Frank C. Baker, curator, Academy of Science.

February 17—"Window Gardening," Aaron H. Cole, Chicago Teacher's College.

February 24—"Beautifying the Schoolyard," Jens Jensen, landscape architect.

March 2—"Trees for the Schoolyard, Street and House, How to Select and Care for them," J. H. Prost, city forester.

March 9—"The Enemies and Diseases of Trees," J. H. Prost, city forester.

March 16—"Birds as Guardians of Trees and other Plants," R. M. Strong, University of Chicago.

WE learn from *Nature* that it is proposed to establish in Dartmouth a permanent memorial to Thomas Newcomen, known for his work in connection with the steam engine, who was born in that town in 1663. A meeting of those interested in the matter has been held in the Dartmouth Guildhall. The mayor of Dartmouth, Mr. Charles Peek, and Mr. T. F. Caston, the honorary secretary to the Newcomen Memorial Committee, will welcome suggestions as to the best manner of perpetuating the memory of the inventor and his invention, and be glad to receive contributions.

THE late Dr. A. S. Packard, of Brown University, planned a series of illustrated volumes on the bombycid moths of North America, to be published by the National Academy. Two volumes were issued during his lifetime. Materials for a third volume, on the large silk-producing moths, were left and these have been placed in the hands of Professor Cockerell, of the University of Colorado, who is editing them for publication.

DR. FRANCISCO P. MORENO, member of the chamber of deputies, Argentina, has introduced a motion in the congress of Argentina for the acquisition by the government, for the

Museo Nacional at Buenos Aires, of the great private paleontological collection of Florentino Ameghino.

MR. JOHN D. ROCKEFELLER has given \$11,000 toward the purchase of the house in which Pasteur was born in the village of Dôle.

PROFESSOR HENRY WILLIAMSON HAYNES, known for his investigations in archeology, died at his home in Boston on February 15, aged eighty years.

DR. HENRY TAYLOR BOVEY, F.R.S., from 1887 to 1909 professor of civil engineering and applied mechanics in McGill University, first rector of the reorganized imperial College of Science and Technology in London, died on February 2, aged fifty-eight years.

SIR HENRY TRENTHAM BUTLIN, Bart., a leading English surgeon and pathologist, died on January 24, aged sixty-six years.

SIR JOHN CHARLES DALRYMPLE HAY, Bart., F.R.S., admiral (retired) of the British navy and the author of books on naval topics, died on January 28, at the age of ninety years.

M. T. DURAND, member of the Royal Academy of Belgium, director of the State Botanic Garden and general secretary of the Royal Botanic Society of Belgium, died on January 12.

THE death is announced of Dr. L. Pič, the noted Bohemian archeologist, in charge of the unsurpassed archeological collection of the Museum Regni Bohemiae, Prague.

DR. OTTO LIEBMANN, formerly professor of philosophy in the University of Jena, has died at the age of seventy-one years.

THERE will be a New York State civil service examination on February 24, the positions opened including that of first assistant veterinarian in the Department of Agriculture at a salary of \$1,800 to \$2,400, and bacteriologist in the Health Officers' Department, Quarantine, New York, at a salary of \$1,500. The latter position is for women.

THE most notable map publication of the year is the large geologic map of North America just issued by the United States Geological Survey. It represents an exceptional

type of engraving and lithographic color work and is printed in four sheets which fitted together and mounted make a map 6 feet 5 inches high by 5 feet wide, the largest piece of work ever issued by the survey. The scale is 1 to 5,000,000, or 80 miles to the inch, and the plan of projection is in harmony with the universal world map on a scale of 1 to 1,000,000, in that it shows the units of publication of the world map, each of which embraces four degrees of latitude and six degrees of longitude. The color scheme of the map is a striking one. In all there are 42 color distinctions, varying from a brilliant red to pale tints approaching white. These were produced by 14 separate printings from lithographic stones, requiring in many places two or three combinations of color to produce the desired effects. If the weight of paper and heavy stones lifted back and forth in the printing of this job were to be computed it would run into the hundreds of tons. The accuracy of the "register," or fitting together of the color blocks in small areas throughout the map, is remarkable. The work was done in the survey's own engraving and printing plant, and it is believed that there are few if any other establishments in the United States capable of turning out such a production. The 42 color distinctions represent as many divisions of rock strata. Thus the rocks of seven divisions of the Paleozoic era are each represented by a color, besides three separate colors for undifferentiated rocks, and there are other colors for the division of the Mesozoic, the Tertiary and the Quaternary. The coloring of the map is both effective and pleasing. The scheme is systematic in that the colors range in prismatic order from yellow in the upper portion of the geologic column through greens, blues and purples to pinks and browns at the base. The colors for the igneous rocks, both plutonic and volcanic, are mostly bright red. Viewed as a wall map, the map of North America shows only the larger geologic units, as the smaller divisions are represented by different shades and tints of the same or closely allied colors which are indistinguishable at a moderate distance.

THE *Journal* of the American Medical Association quotes from the *Journal Officiel* data of the vital statistics in France for the first semester of 1911. There were almost 14,000 fewer births than during the corresponding semester of 1910. Last year the births, which were few enough already, amounted to 399,669. This year there were not more than 385,999. While births diminished, deaths increased. They increased from 378,480 during the first semester of 1910, to 404,278 during the first semester of 1911, an increase of 25,798. During the six first months of the current year the deaths exceeded the births by 18,279. The number of marriages has decreased in a slightly less proportion. There were about 156,761 last year. There are not more than 153,931 this year. Divorces, which last year amounted to about 6,303, in 1911 have increased to 6,374.

THE fourth report of the royal commission on university education in London deals with the housing of London University. According to the London *Times* the commissioners state that it had become clear, as the inquiry proceeded, that the inception of any scheme which they might be able to recommend and which parliament might sanction would be seriously delayed unless some steps had previously been taken to provide for the university, as reconstituted, a site and buildings more convenient and adequate than those it now occupied. They think that whatever its future constitution might be, it was a matter of national importance that the University of London should be recognized and adopted as a great public institution; and that it was fitting and right that such an institution should have for its headquarters permanent buildings appropriate in design to its dignity and importance, adequate in extent and specially constructed for the purpose, situated conveniently for the work it had to do, bearing its name, and under its own control. The University of London, it is stated, must depend, like other universities, to a large extent, for the liberal support necessary for its full development upon the endowment of private benefactors. The commissioners thought such benefactors

were to be found; and the inquiry had impressed them so forcibly with the almost unlimited possibilities of the university in the future, that they could not easily conceive a more splendid opportunity than its endowment and the provision of a noble and suitable building for its home afforded for the liberality of the citizen.

ATTENTION is called in the *London Times* to the fact that every year the London Zoological Gardens are visited by large numbers of school children, accompanied by their teachers. The price of admission for these is one penny, and the time spent on the visit is counted as school attendance. The council of the society desired to make these visits more useful, and last year arranged with the education committee of the London County Council for a series of demonstration lectures to school teachers. The Zoological Society arranged the courses, provided the lecture-room and lantern and allowed the teachers free admission to the gardens, while the education authority made a grant towards the expenses. The course, which was repeated three times last session to three separate sets of 150 school teachers, consisted of three lectures illustrated by lantern slides and a demonstration in the gardens, for the latter the teachers being divided into parties of 25. This session it was considered advisable to increase the number of demonstrations in the gardens, and the education committee has increased their grant to make this possible. The syllabus has been made very simple and is devised to cover only such subjects as may be made interesting to school children. In the case of mammals the main types, such as carnivores and herbivores, are considered in relation to their food and modes of obtaining it, their weapons of offence and defence and their chief adaptations to their environment. Birds are similarly treated, but the nesting habits and the care of the young are discussed more fully. The coloration of animals in relation to deserts, snow and so forth are dealt with, and salient examples of mimicry and warning patterns and colors are pointed out. In the demonstration tours in the gardens examples of the questions dis-

cussed in the lectures are pointed out. The first lecture for the season was attended by nearly 150 teachers, while four parties of 25 teachers were taken for a demonstration tour in the gardens by the lecturer, Mr. J. L. Bonhote, and his assistant, Mr. J. T. Cunningham. To suit the convenience of teachers, all the lectures and demonstrations are given on Saturday mornings, and the three courses now arranged for will last well on into the early summer of next year.

THE first All-Slav Congress and Exposition of Social Medicine and Hygiene will be held in St. Petersburg during the week commencing May 28, 1912. There will be five sections, the first of which (president, V. O. Gubert), will deal with medicine and hygiene of the masses; the second (president, J. F. Zemackij), with gymnastics and exercises tending towards the better development of the body; the third (president, M. M. Kovalevskij), with social ethics; the fourth (president, A. V. Vasiljev), with the development and health of the child, and the fifth (president, D. O. Ott), with the woman. More in detail, Section 1 will deal with regulation of the medical aid; hygiene of houses and cities; housing problems; nourishment, with price of food; social and hygienic protection of workingmen; combat of prevalent diseases; protection of the mental health of the population; medical education and activities, and cure establishments, springs, etc., with balneotherapy. Section 2 embraces physical exercises; the Sokols (the great Slav gymnastic organization); athletic contests and sports; touristic, and bathing, with swimming. Section 3 deals with abuse of alcoholic beverages; dissipation and specific diseases; suicide, and criminality. Section 4 extends to development of the child; health in infancy; infant mortality; training of the child before school age; school hygiene, and mental development of the child. Section 5, finally, embraces everything relating to the functions and health of the woman.

THE *American Museum Journal* states that in revising the installation of the New Guinea material in the South Sea hall, Dr. Lowie is making extensive use of the sketches secured

by the museum with the Finsch collection. Dr. Otto Finsch, the celebrated naturalist and traveler, provided with the collection a very full series of illustrations accurately picturing many phases of native life. These are highly desirable, as many aspects of aboriginal culture, such as house and boat types can not always be readily transported or even secured in model specimens, although often they form the most characteristic elements of the culture of a tribe. This applies even more emphatically to social and ceremonial life, which can be studied very inadequately, if at all, from museum specimens. It also applies in large measure to objects of personal adornment and clothing. For instance, it would not be at all obvious to the average visitor how the aborigines wore a profusely decorated heart-shaped object conspicuously exhibited in one of the New Guinea cases. A glance at the sketch now beside the specimen shows it to be a warrior's breast ornament. Similar results have been accomplished with other articles of dress which otherwise could not readily be understood except with the aid of long explanatory labels.

THE *London Times* states that in the old parish church of St. Mary, Teddington, a tablet has recently been dedicated to the memory of the Rev. Stephen Hales, D.D., a former vicar of the parish and one of the most distinguished men of science of the eighteenth century. A number of eminent living *savants* have for a long time been endeavoring to discover his burial place, in order to preserve his memory, and at length the stone recording his death was found in the floor of the porch of the church with nearly the whole of the lettering obliterated. The new tablet has been placed on the wall of the west porch beneath the tower of the old church, and bears the following inscription:

Beneath is the grave of Stephen Hales. The epitaph, now partly obliterated, but recovered from a record of 1795, is here inscribed by the piety of certain botanists, A.D. 1911. "Here is interred the body of Stephen Hales, D.D., Clerk of the Closet to the Princess of Wales, who was minister of this parish 51 years. He died 14th January, 1761, in the 84th year of his age."

Mr. Francis Darwin has written for the current number of the *Parish Magazine* an interesting account of Dr. Hales, in the course of which he says: "Stephen Hales has been called the 'father of physiology,' and he deserves this title in regard both to animals and plants. His experiments on the blood pressure of animals are second only to Harvey's work on the circulation. In the domain of plant physiology he is equally great. In all his researches he combined a belief in the design of the Creator with a passionate desire to understand the mechanism of living things. Thus he treated the manifestations of life as things to be weighed, measured and analyzed in the laboratory. It is this point of view that gives his work so modern a character and entitles him to be considered one of the founders of a rational science of biology. Although he loved science for its own sake, it is equally clear that he was dominated by a permanent desire to use his knowledge for the benefit of his fellow-creatures. Water supply, ventilation, the distillation of potable water at sea, the preservation of food on long voyages, the treatment of at least one disease—the stone—and especially the harm arising from intemperance in the use of alcohol, all received attention. It is impossible to read his works without mingling personal affection with the respect inspired by his intellect."

UNIVERSITY AND EDUCATIONAL NEWS

AFTER long preparation, ground has been broken for the first Reed College buildings on the campus of eighty acres. The college will open next September in the permanent buildings, and on the endowment foundation of about \$3,000,000 provided by Mr. and Mrs. Simeon G. Reed, of Portland. Three buildings, in addition to residences for the faculty, will be ready—the arts building, the dormitory and the gymnasium. All the buildings will be in the collegiate-gothic style of architecture. The material will be Indiana limestone and mission brick. The arts building and dormitory will be of steel and concrete structure, fireproof throughout. The buildings will run against the wooded ravine and lake, which

are picturesque features of the campus. The arts building is 257 feet long, with wings 85 feet long. It has four stories. The estimated cost of the building and furnishings is \$225,000. The dormitory, which is virtually five separate dormitories, contains a large clubroom for men students, a dining-hall and rooms and baths for 125 students. The cost of this building, exclusive of furnishings, is \$140,000.

THE plan of George M. Pullman for the establishment of a manual training school at Pullman, Ill., is assuming definite form. Professor L. G. Weld, formerly professor of mathematics and dean of the University of Iowa, has been despatched on a tour of America and Europe to collect data to guide the board of trustees in the construction of the buildings and the arrangement of the curriculum. Building operations, it is expected, will be commenced next year. A site of forty acres has been purchased at a cost of \$100,000. A fund of \$1,000,000 was bequeathed by Mr. Pullman at his death on October 18, 1897, for founding the institution. This fund was invested in securities which have increased in value until now there is about \$2,500,000 at the disposal of the directors for the school.

THE University of California announces the establishment by Mr. F. M. Smith, of Oakland, California, of a research fellowship for investigation of certain problems incident to the growth of cities in the San Francisco Bay region. Attention is to be directed especially to questions relating to the development of parks, playgrounds and other community interests demanding particular consideration of space available for growth. The stipend of the fellowship is \$1,000 per annum, and an additional sum of \$500 annually is provided for expenses of the investigation. The work of the fellow will be conducted under the supervision of a special committee named for this purpose, and the results worthy of record are to be prepared for publication.

\$12,500 was recently turned over to the authorities of the Colorado School of Mines for the equipment of the new ore testing plant. The building for the plant was built a year

ago and \$50,000 was allowed by the legislature for the necessary machinery and one fourth of this is what is now available. Many donations of machinery have been made by the various manufacturers and it will now be possible to completely equip, ready for operation, the concentration section of the plant.

DR. J. B. HURRY has established a research studentship of physiology at Cambridge to be named in honor of Michael Foster.

WE learn from the *Bulletin* of the American Mathematical Society that Dr. G. Schirmer, a Chicago physician, has established at the University of Erlangen, a prize fund, to be known as the Helene Otilie Schirmer foundation, in honor of his late wife. The income, \$150, is to be given to the author of the most meritorious thesis prepared at the university during a period of two years preceding each award; the subjects are to be in mathematics or physics in odd years, and in medicine in even years. The first award has recently been made to Dr. R. Baldus for his dissertation on certain line congruences.

Two new departments are to be established at Swarthmore College next year, one in political science, and the other in psychology and education. Dr. Robert C. Brooks, at present professor of political science at the University of Cincinnati, is to head the political science department, and Dr. Bird T. Baldwin, now professor of education at the University of Texas, will have charge of the work in psychology and education.

DR. C. N. JENSEN, fellow in plant pathology, Cornell University, has been appointed professor of botany and plant pathology in Utah Agricultural College and Experiment Station and entered on his duties on February 1.

DR. ELEANOR H. ROWLAND, professor of philosophy at Mt. Holyoke College, has resigned to become dean of women and professor of philosophy at Reed College, Portland, Ore., but does not enter upon her new duties until next September. She will spend the next semester in Crete, engaged upon research work. Dr. Kate Gordon takes Dr. Rowland's place during the second semester.

DR. SAMUEL P. HAYES, professor of psychology, will be in England until next fall.

MR. C. SHEARER, of Clare College, Cambridge, has been nominated to a newly established lectureship in experimental morphology at Cambridge.

DISCUSSION AND CORRESPONDENCE

THE WORD GENOTYPE

PROFESSOR JENNINGS (SCIENCE, December 15, p. 847) refers to the fact that the word *genotype* has two meanings, but does not make it quite clear that both are current at the present time. The use of the word, with a definition, by Schuchert antedates that of Johannsen, as has been several times pointed out. Taxonomists can hardly be expected to abandon their prior and useful term, so it becomes a question whether it is convenient to continue the Johannsenian usage, trusting to the context to indicate in every case what is intended.

Some months ago, in conversation, my colleague, Dr. George Norlin, suggested "*amictotype*" as a possible substitute for *genotype* in the sense of Jennings.

T. D. A. COCKERELL

UNIVERSITY OF COLORADO

GENOTYPE AND "GENOTYPE"

"IN calling attention to the frequent misuse of the word '*genotype*'" (quotation from George H. Shull in SCIENCE, February 2, 1912, p. 182), the students of heredity will please take notice that this term has been in biology since 1897 and that Shull, Johannsen and others persistently misuse the term. The original definition is as follows:

"*Genotype* (*genos* = race, and *typos* = type).—*Genotype* applies to any *typical material of the type species of a genus*. The material, however, should be, if possible, from the original locality of the species, or a *genotype* should also be a *topotype* or a *metatype*. Therefore there may be as many *genotypes* of *Lingula* as there are museums having characteristic specimens of *Lingula anatina*."¹

CHARLES SCHUCHERT

SCIENTIFIC BOOKS

Lectures on Fundamental Concepts of Algebra and Geometry. By JOHN WESLEY YOUNG, Professor of Mathematics in the University of Kansas. Prepared for publication with the cooperation of WILLIAM WELLS DENTON, Assistant in Mathematics in the University of Illinois. With a Note on the Growth of Algebraic Symbolism by ULYSSES GRANT MITCHELL, Assistant Professor of Mathematics in the University of Kansas. New York, The Macmillan Company. 1911. Pp. vi + 247.

Descriptive Geometry: A Treatise from a Mathematical Standpoint. By VICTOR T. WILSON, M.E., Professor of Drawing and Design in the Michigan Agricultural College. New York, John Wiley & Sons. 1909. Pp. viii + 237.

Elements of Descriptive Geometry with Applications to Spherical and Isometric Projections, Shades and Shadows, and Perspective. By ALBERT E. CHURCH, LL.D., late Professor of Mathematics in the United States Military Academy, and GEORGE M. BARTLETT, M.A., Instructor in Descriptive Geometry and Mechanism, University of Michigan. New York, American Book Company. 1911. Pp. 286.

Professor Young's "*Lectures*" presuppose in the reader intellectual acumen and a certain logical bent but little mathematical knowledge beyond the elements of algebra and geometry. Dealing with such topics as Euclid's *Elements*, A Non-Euclidean World, Consistency, Independence and Categoricalness of a Set of Assumptions, with the notions of class, correspondence and group, the assumptions of Hilbert and Pieri, dimensionality and hyperspace, variable, function and limit, and dealing with them in a way that is at once philosophic, romantic, scientific and well-nigh literary, the lectures ought to appeal to a wide and diversified class of readers, philosophers, logicians, both expert and inexperienced mathematicians, and thinkers in general. The book is far more than its title indicates, for the concepts treated are presented as being fundamental to mathematics in general, to

mathematics regarded as "the universum of exact thought," rather than to algebra and geometry conceived as special branches thereof. Basic concepts and central concepts, though the two categories may intersect, are in general not the same, else the book would doubtless have admitted to a prominent place the notion of invariance, a notion that, besides being of central importance in mathematics, serves to ally the interests of this science with those of science in general, and with those of philosophy, theology, religion and art. It is the chief unifier of the great forms of human interests and endeavor. Professor Young has admirably shown that any science must contain two sorts of ideas, the assumed and the defined; besides these it uses ideas that it does not contain (as subject matter); the like is true of propositions; somebody ought, in respect of some science, to assail the problem of indicating those ideas that are used by the science without being a part of its content. In the chapter dealing with "the logical significance of definitions" Professor Young might well have said, what he doubtless knows, that, for example, the notion of definition is no part of the subject matter of logic or mathematics, though for the sake of convenience the notion is continually there in use. The conception of mathematics presented in italics on page 221 leaves the science without any unity except such as belongs to a mere collection, which can never satisfy. The defect is partly cured on page 225. In a democracy it is a duty of scholars to render scientific concepts intelligible to the public intelligence, and Professor Young's book is a valuable contribution to such high service.

The descriptive geometry treated by Professor Wilson and Professor Bartlett is not to be confounded with that great variety of geometry, called descriptive by Russell and others, which was founded by Pasch in his "Vorlesungen über neuere Geometrie" (1882) and a few years later cast in symbolic form by Peano, but it is that branch of geometry which has for its object the representation of

3-dimensional figures by means of their projections upon two or more planes, a method invented by Gaspard Monge (a peddler's son) in response to military exigencies in France and set forth by him in 1800 in his "Géométrie descriptive." Professor Wilson's aim, "to present a sound theoretical treatment" and not to win the student by means of mere appeal to "short cuts" and his "practical" interest, is laudable. As to the extent to which the end has been attained, some mathematicians may be disappointed in not finding here a system of postulates. On the same page (2) we are told that parallel lines are said to have two points in common at infinity, that parallel planes meet each other in a common line at infinity, and that descriptive geometry and perspective are a part of projective geometry. The traditional use of "line" for curve is adopted. Two consecutive points are regarded as points "infinitely close" together but not coincident (p. 81) and as coincident points (p. 93). The statement that "the secant approaches tangency and become such when the two points [of secancy] become coincident" will serve (even after typographical correction) to exemplify a not infrequent occurrence in the book of unprecise statement. One can not but feel that so good a book ought to be better. Typographically and mechanically it is pleasing; there is appended a goodly list of exercises; and the point of view is somewhat more general than is common in American text-books in this subject.

When will some breath of modern mathematics get into our text-books of descriptive geometry? Church's "Elements," published in 1864, has reigned, partly because of its merits, for nearly five decades. To meet the new demands in respect of matter and of presentation, Professor Bartlett has not deemed it necessary to depart essentially from the venerable text of Church. Consequently this interesting and instructive new volume has the scientific odor of a geometric past, despite the excellence of the drawings and pictorial representations of certain more

difficult problems. On page 63 we are invited to think of a moving point as going from one position to the "next." Two points thus next to each other *form* an infinitely small straight line. The two points are consecutive, without distance between them, and "may practically be considered as one point." No talk about limit: a curve is, for thought, composed of infinitely short straight lines. The term locus does not appear except incidentally as on page 84. But "if a point moves so as continually [not continuously] to change its direction from point to point, the line generated is a curved line, or curve." According to the highest mathematical standards, descriptive geometry has not attained, in America, to the rank of a science. It is a tool. Judged as a work designed to teach the use of an important tool, Professor Bartlett's book will render good service. But such books ought to get up-to-date in respect to logic, geometric spirit, conception and nomenclature.

COLUMBIA UNIVERSITY

C. J. KEYSER

Les Poissons Wealdiens de Bernissart. By RAMSEY H. TRAQUAIR, M.D., LL.D., F.R.S. Extrait des Mémoires du Musée Royal d'Histoire Naturelle de Belgique, T. VI. Bruxelles. 1911. 4to. Pp. iv + 65; 12 pls. and 21 text figures.

In this memoir Dr. Traquair—the dean of paleichthyologists—discusses the fishes of the Wealden, or basal Cretaceous, of Belgium. This formation, though known chiefly for fine skeletons of the dinosaur *Iguanodon*, contains also a highly interesting fish-fauna. This is remarkable for the fact that its species, though relatively few (sixteen), represent both the more archaic members of the group of ganoids as well as the quite modern teleosts. In discussing this fauna, therefore, Dr. Traquair has opportunity of reviewing at once such forms as *Coccolepis*, the last survivor of the Palæoniscidæ, as well as *Leptolepis*, the earliest of the clupeoids.

The memoir is of necessity devoted mainly to systematic details; none the less broader questions, such as those of morphology, relationship and geological distribution, are not

overlooked. And all these themes are treated with the author's characteristic painstaking regard to fact. In short, the memoir is an example of what a systematic review of a fossil fauna should be.

An interesting and very useful feature is the carefully drawn restorations, of which there are thirteen. Especially noteworthy are those of *Coccolepis*, *Callopterus*, *Amiopsis*, *Mesodon* (with new interpretations of the cranial elements) and *Aethalion*. These figures are sure to follow the many others from the same hand, and become part of the stock in trade of all writers on ichthyology.

The fauna of Bernissart, as a whole, is regarded as fresh water. The chief evidence for this view is the entire absence of sharks from this formation, although the group is abundantly represented in other European rocks of equivalent age.

To the friends of Dr. Traquair—and they are many, both in Europe and America—the publication of this memoir has an especial interest. For it shows the doctor, who is past his seventieth anniversary, still working away, with his old-time vigor and enthusiasm, in the field which he has done so much to advance.

Ave Magister! Many be the years

That lie before thee, thronged with busy hours!¹

L. HUSSAKOF

AMERICAN MUSEUM OF NATURAL HISTORY

THE HARRIS TIDAL MACHINE

THE Coast and Geodetic Survey has recently put in operation, after a thorough test, a new tide-predicting machine, which performs simultaneously all the operations of the British or Thomson machine and of the first American machine invented by Professor Ferrel. As in the Thomson machine, the tidal curve is drawn from which the height of the tide at any time may be scaled off, but, in addition to this, the times of high and low water are marked upon its axis, and both the time and height of the tide, as well as the height of the water's surface at any given

¹Dr. S. Weir Mitchell, "The Comfort of the Hills and Other Poems," p. 95. New York, 1910.

time, are shown upon graduated circular dials on the face of the machine. The machine was invented by Dr. R. A. Harris, who seventeen years ago published a brief but comprehensive description and submitted a general plan to the Coast Survey Office. (See report of superintendent for 1894.) The details of the machine-design were worked out by Mr. E. G. Fischer, under whose direction the machine was set up in the instrument division of the survey.

Mechanical aids of this kind are used in connection with the tides, because good predictions require the combination of a considerable number of sine or cosine terms whose arguments vary uniformly with the time. The new machine contains 32 short-period components (*i. e.*, daily, semi-daily, quarter-daily, etc.) and 7 having long periods (*i. e.*, fortnightly, monthly, semi-annual and annual).

In combining these numerous terms two summations are carried on continuously by means of two chains each fixed at one end and free to move at the other. Each chain is laid alternately over and under a series of pulleys whose upward and downward movements cause the free end of the chain to travel back and forth across a fixed initial point. The motion of the free end of one of the chains is proportional to the rise and fall of the tide to be represented or predicted; that of the free end of the other chain (or rather of a marked link a certain distance from this end) is such that when this link passes across a fixed point the height represented by the first chain is at its maximum or minimum value. These statements describe very briefly the general plan upon which the times and heights of the tides are mechanically determined. As already stated the times and heights are shown upon the face of the machine while a curve is drawn which makes a permanent record of all stages of the tide.

The machine is driven by hand and the gears are such that the periods of motions which depend upon them shall represent the known periods of the various sine and cosine terms into which tidal records or observations can be resolved.

In the new machine the error resulting from the representation of the incommensurable astronomical ratios by the gears amounts to less than one degree for a period representing a year in prediction. For the larger terms the error is much less, so that after predicting a year's tides and reading hourly heights for December 30 and 31, the predicted values agreed so well with the values computed directly from astronomical data, as to make the errors negligible.

It may be stated that, although tide-predicting is the most useful purpose to which the machine is put, its broadest application is in the solution of equations of the form $y = H_0 + A \cos(at + \alpha) + B \cos(bt + \beta) + \dots$, where A, B, C, \dots denote the amplitudes and a, b, c, \dots their speeds per unit of time t , of which it draws the graph and indicates the positions and magnitudes of the roots.

SAMUEL TIERNEY, JR.

SPECIAL ARTICLES

XERALEXIS

WHOEVER brings forward a new word must show what the students in journalism would call a "crying need" for it, or take the consequences. The undersigned is not altogether certain as to how crying the need may appear to others, but it seems to him that a single euphonious, appropriate word should be sought to replace the clumsy and rather ill-sounding compound, "drought-resistance." The writer proposes the coining of the word *xeraléxis*, from the Greek *ξηρότης*, drouth, and *ἀλξιησις*, a keeping off or resistance.

We have, of course, the words, "xerophytic" and "xerophytism," which do not, however, involve the idea of resistance to drouth in their composition, and do not convey that meaning in usage, although it stands to reason that a "drouth-resistant" plant will have "xerophytic" characteristics of some kind.

There is ample justification for the new word on etymological grounds. The Greeks had many compounds in which the above roots were employed. The root of the adjective *xēros*, "dry" and *xērólēs*, "drouth," is found

in *xerophthalmia*, a dryness of the eyes; *xerobiotikós*, living on dry land; *xerophagia*, the eating of dry food, etc.

The root of the word *aléxein*, "to ward or keep off, to turn away or aside," and *aléxēsis*, "resistance or warding off," is found in such combinations as *alexanemia*, "shelter from the wind," or where Sophocles in the *Œdipus*, uses the adjective *aleximoros*, "warding off fate or death" (*μός*). Hipparchus uses *alexipharmakos*, in the sense of "warding off poison," or "acting as an antidote."

So the examples might be multiplied. It is strange that the Greeks did not themselves coin a word for "drouth-resistance," for they had and have an abundance of drouth to resist in Hellas, as any one who has ever been there in the summer-time can abundantly testify. It would be interesting to investigate modern Greek terminology on this point.

A euphonious compound of the two above roots can only be made by putting the root for drouth first; although the Greek tendency in the formation of compounds involving *aléxein*, in the sense of "warding off," "defending," seems to put the latter first, as in *Aléxandros* (Alexander)—defender of men (*anēr*, man)—in the examples given above, and many others. To follow this practise and coin such a word as *alexixerótēsis* might be possible for a Greek, but not for us.

Let us accordingly turn the roots around. We then find that we have available for the first member of the compound, two possible nouns, viz., *aléxēsis* (*ἀλέησις*)—"a keeping off" or "resistance," and *aléxis* (*ἀλέξις*) "help"—both from the same root as the verb *alexéo* or *aléxō* (*ἀλέξω*, *ἀλέξω*), infinitive *aléxein* (*ἀλέξω*)—a verb which has both the primary signification of to "ward off" or "resist" and the derived one of "to help." Here we encounter a difficulty. If we follow a natural analogy and say *xeraléxis*, following "prophylaxis" from the Greek *phulaxis* (*φύλαξις*), a "watching" or "guarding," then we seem to imply a derivation from the word *aléxis*, "help," rather than from *aléxēsis*, "warding off." But on the other hand, "*xeraléxēsis*" is slightly longer than

"drouth-resistance." There remains, of course, the possibility of following another valid Greek analogy, and saying *xeraléxia*.

On the whole, however, *xeraléxis* is preferable on the score of brevity and ease of pronunciation. Perhaps we are justified in calling it a "contract form" of "*xeraléxesis*," if that will satisfy the philologists.

We then have for "drouth-resistance," *xeraléxis* and for "drouth-resistant," *xeraléctic*. In the writer's estimation these words might well replace in botanical language generally, not only our English compound, but the awkward French *résistance à la sécheresse*, or the German *Austrocknungs-resistenz*. At all events the new word is logical—as logical as "ecological" in fact.

H. F. ROBERTS

CRYPTOBRANCHIUS ALLEGHANIENSIS, LARUS ATRICILLA AND LARUS MARINUS IN NORTH DAKOTA

IN a recent article,¹ Pope has recorded the hellbender (*Cryptobranchus alleghaniensis*) and the laughing gull (*Larus atricilla*) as abundant, and the black-backed gull (*Larus marinus*) as occasional at Devils Lake, North Dakota. These records, if verified, would be of much interest, extending the range of the hellbender to the northwest of that hitherto recognized and bringing the laughing and black-backed gulls from the Atlantic coast far into the interior. In three summers spent in this region, however, I have been unable to verify Pope's records and seriously question their accuracy, both for this reason and because of their inherent improbability.

Franklin's gull (*Larus franklini*) a bird which might readily be mistaken by an inexperienced observer for the laughing gull (*L. atricilla*) is a common breeder in this locality, after the breeding season gathering in large flocks upon the lake. Pope has probably mistaken the ring-billed gull (*Larus delawarensis*) for the black-backed (*L. marinus*). I

¹ Pope, Thomas E. B., "Devils Lake, North Dakota. A Study of Physical and Biological Conditions with a View to the Acclimatization of Fish," Bureau of Fisheries Document, No. 634.

have not taken specimens of the former and hence can not speak positively of its occurrence. It has been recorded, however, by competent field observers,³ and since its recognized breeding range includes North Dakota, while that of the latter is the northern Atlantic coast, its occurrence here is far more probable than that of the latter.

The only common salamander in the lake is *Amblystoma tigrinum*, which occurs in considerable numbers. I have seen no specimens of *Cryptobranchus* from the lake, and unless Pope's record is supported by specimens, it must be regarded with grave suspicion.

ROBERT T. YOUNG

UNIVERSITY OF NORTH DAKOTA

THE AMERICAN MICROSCOPICAL SOCIETY

THE meeting of the American Microscopical Society at Washington was purely a business session. The following officers were elected: *President*, Professor F. D. Heald, University of Texas; *First Vice-president*, Professor F. Creighton Wellman, Tulane University Medical School; *Second Vice-president*, Mr. Edward Pennock, Philadelphia, Pa.; *Custodian*, Mr. Magnus Pfau, Meadville, Pa. Professors A. M. Reese, University of West Virginia; P. C. Waite, Western Reserve Medical School, and W. F. Mercer, of Ohio University, Athens, Ohio, were chosen elective members of the executive committee. Professor T. W. Galloway, Millikin University, and Dr. Brayton H. Ransom, of Washington, were elected to represent the American Microscopical Society in the council of the American Association for the Advancement of Science.

The business of prime importance was the determination of the future use of the Spencer-Tolles Fund for the encouragement of research, which now amounts to about \$3,500. The fund has been allowed to accumulate for a number of years without any productive use. It was agreed (1) that proper steps should be taken to safeguard the fund in case of the failure of the society; (2) to use the fund to encourage research within the society; (3) to begin the productive use of the fund at once, so that its memorial character may be realized.

More than one hundred new members and sub-

scribers have attached themselves to the society during the year, and 1912 gives promise of being the most successful and prosperous in the history of the society.

In the absence of the president, Dr. A. E. Hertzler, Professor C. E. Bessey presided over the meeting of the executive committee, and Professor M. J. Elrod over the business session.

T. W. GALLOWAY,

Secretary

THE SOUTHERN SOCIETY FOR PHILOSOPHY AND PSYCHOLOGY

THE seventh annual meeting of the Southern Society for Philosophy and Psychology was held at Washington, D. C., on Wednesday, Thursday and Friday, December 27, 28 and 29, 1911, in conjunction with the American Psychological Association and the American Association for the Advancement of Science. The meetings were held in the George Washington University Medical School, President Shepherd Ivory Franz presiding. The programs for December 27 and 28 were arranged jointly with the American Psychological Association. Following the joint meeting on Thursday afternoon came the president's address on "New Phrenology." On Thursday evening the members of both societies were entertained at a smoker held at the New Fredonia Hotel by Professors Franz and Ruediger.

The following items were passed upon at the business meeting held on Friday morning, December 29:

1. The proposed amendment to Art. II, Sec. 3, of the constitution was adopted.
2. It was resolved that the existing arrangement with the Psychological Review Publishing Company be continued as optional to the members of the Southern Society and be handled as hitherto by the secretary of the society. In the future, however, this option is available only to members residing in the southern territory, but it is no longer restricted to those who are new subscribers. Notice of the above arrangement is to be printed after the constitution on the membership list.
3. The secretary was authorized to drop the names of members after one year of delinquency.
4. The determination of the time and place of the next meeting was left in the hands of the council.

5. The treasurer's report was audited by the council and showed a balance on hand, December 23, 1911, of \$65.64.

³ Messrs. Alf Eastgate, of Tolna, and Elmer Judd, of Cando, N. D.

6. The following officers were elected for the year 1912: *President*, Robert Morris Ogden, University of Tennessee; *vice-president*, H. J. Pearce, Brenau College, Gainesville, Ga.; *secretary-treasurer*, William Carl Ruediger, The George Washington University; *councilors*, Shepherd Ivory Franz, John Brodus Watson (for 3 years) and W. B. Lane (for 1 year).

7. The following persons were elected to membership: Samuel Claman, Howard University; H. E. Cunningham, Lookout Mountain, Tenn.; Gardner C. Basset, Johns Hopkins University; Willis-ton S. Hough, George Washington University; Edmund B. Huey, Johns Hopkins University; Herbert Charles Sanborn, Vanderbilt University.

8. Votes of thanks were extended to Dean W. C. Borden for the use of the George Washington University Medical School and to Professors Franz and Ruediger for the smoker.

THE GEOLOGICAL SOCIETY OF AMERICA

THE twenty-fourth annual meeting of the Geological Society of America was held at the new National Museum at Washington, D. C., from Wednesday to Saturday, inclusive, of Christmas week, and was the largest in the history of the organization, there being a registered attendance of 140 fellows and 14 fellows-elect, besides many visitors. Professor William Morris Davis, president for the year, presided, having made a special trip for the purpose to America from Paris, where he is serving as Harvard exchange professor at the Sorbonne. The first session of the society was occupied with matters of business. The secretary reported the election of twenty-nine new fellows, making the present active membership of the society 351.

During the past year, there were lost by death Samuel Calvin, for many years state geologist of Iowa; Samuel F. Emmons, a noted mining engineer who was connected with the United States Geological Survey from its organization and was a member of the National Academy of Sciences; Christopher W. Hall, professor of geology at the University of Minnesota; Edwin E. Howell, of Washington, D. C., and Amos O. Osborn, of Waterville, N. Y. One foreign correspondent, Professor A. Michel-Lévy, a famous French geologist, died. An indication of the activity of the society was the publication during the year of a volume of its *Bulletin*, consisting of 738 pages of text and 31 plates, and including part of the papers read at

the last preceding annual meeting, which was held at Pittsburgh a year ago. A large part of the volume was devoted to E. O. Ulrich's contribution, "A Revision of the Paleozoic Systems."

In the course of the meeting the following papers were offered:

New Evidence on the Taconic Question: ARTHUR KEITH.

The reasons were given in this paper for reopening the old controversy and for selecting the north end of the Taconic Mountain as the crucial place. The principal views regarding the rocks of the Taconic Mountains were briefly outlined and the geology of the region summed up. Five subdivisions of the Stockbridge limestone around the north end of the Taconics were described and attention called to the extreme folding and metamorphism of the rocks. The slates of the mountains are sharply outlined from the Stockbridge limestone and the contact follows a rude semi-circle around the end of the mountains. The characters of this plane of separation were discussed and the conclusion reached that they can only be due to faulting. The bearing of this conclusion was briefly considered.

Some Features in the Grand Canyon of Colorado River: N. H. DARTON.

Several years ago, the author measured sections at a number of points along the Grand Canyon to determine the stratigraphy of the Arizona Plateau. These sections were presented, and there was exhibited a colored preliminary geologic map of the Vishnu, Bright Angel and Shinumo quadrangles similar to one now in the corridor of El Tovar hotel at Grand Canyon.

Covey Hill Revisited: J. W. SPENCER.

This remarkable hill terminates the northeastern point of the Adirondack plateau (1,030 feet above tide). It is capped with Potsdam sandstone thinly covered with drift. This hill is separated from the main plateau by a broad depression from which the drift has been swept away. Its removal is commonly attributed to the broad trough being a spill-way for a glacial lake. This question is not raised except that it may have belonged to an epoch before the Iroquois period. The broad trough is incised by a deep gorge—the Gulf. Its character has not been fully described. This heads in a small channel such as is being formed to-day, with the increase in size due to the undermining of the walls of jointed sandstone where the blocks are forced off by frost action. Thus the gorge can not be taken as evidence of a greater drainage

than at the present time. The gorge is post-Glacial for this reason, and does not represent the outflow from a glacial lake. A beach on the northern flank of the hill at 450 feet above tide has been supposed to be marine without the showing of any evidence. Upon revisiting the hill no evidence of the marine character was found.

Dr. Spencer's paper was discussed by J. B. Woodworth and H. L. Fairchild, and reply was made by the author.

Pre-Cambrian Formations in South-central British Columbia: REGINALD A. DALY.

A reconnaissance along the Canadian Pacific Railway line has established the following conclusions: (1) Dawson's "Nisconlith series" occurring in the Selkirk Mountains is not Cambrian, but represents the northern continuation of the "Beltian" (Belt terrane) rocks at the International Boundary. (2) Dawson's "Nisconlith series" of the Shuswap Lakes area (west of the Selkirks) is an entirely different pre-Cambrian and pre-Beltian group of sediments, which unconformably underlie the "Nisconlith series" of the Selkirk section. (3) The Adams Lake volcanic series conformably overlies the thick limestones of the "Nisconlith series" in the Shuswap Lakes area and is of pre-Beltian age. (4) The "Shuswap series" of the Shuswap Lakes is not a distinct gneissic group unconformably underlying the "Nisconlith series," but is the facies of the "Nisconlith series" produced where that series was thermally metamorphosed by batholiths. (5) Though these pre-Cambrian rocks are typical crystalline schists, their metamorphism of the regional type was not due to dynamic action; it was "static" metamorphism (*Belastungs-metamorphismus* of Milch). (6) The pre-Cambrian rocks are much less deformed (upturned) than the overlying Carboniferous or Triassic rocks, illustrating the small depth of the earth-shell which underwent strong folding in post-Cambrian time. (7) The petrography of this pre-Cambrian and pre-Beltian terrane strongly suggests that it furnished the greater part of the clastic material of the Rocky Mountain geosynclinal prism.

Origin of the Sediments and Coloring Matter of the Eastern Oklahoma Red Beds: J. W. BEEDE.

Recent investigations seem to show that the sediments of the lower red beds of Oklahoma were derived from the Arbuckle-Wichita Permian land mass. The conclusion is based on the amount of material removed and the geographic distribution of sediments bordering the mountains. Coarse

limestone conglomerate of great thickness and conglomerates of crystalline rocks—both possibly of subaerial origin—dovetail into red beds. Belts of sandstone have been found extending into the area of finer sediments farther away from the mountains, apparently indicating the location stream debouchures at the margin of the shoal sea. The extreme shallowness of the water is clearly indicated in the structure of the beds. The coloring matter is thought to have been derived from the solution of the 8,000 or 10,000 feet of pre-Carboniferous limestone which formerly covered the Arbuckle-Wichita Mountains and much of the surrounding region. The solution of the limestone furnished optimum conditions for the oxidation of its iron content, as it does at the present time in the limestone regions of the Mississippi Valley, southern Europe, West Indies, etc. Moreover, the solution of the pre-Carboniferous limestones and the conglomerates of the Arbuckle-Wichita region now in progress produces a red residuum practically indistinguishable from red beds sediments. The red granites, red porphyries and other crystalline rocks of the region under discussion contributed their share of material to the red beds. Other factors may have entered largely into the formation of the red beds of western Oklahoma.

The paper was discussed by I. C. White.

Correlation of Rocks in the Isolated Coal Fields around the Southern End of the Rocky Mountains in New Mexico: WILLIS THOMAS LEE.

Several isolated coal fields in New Mexico, near the southern end of the Rocky Mountains, were visited, notably those near Cerrillos east of the Rio Grande and those on the Rio Puerco. Stratigraphic studies were made and fossil leaves and shells collected from the coal-bearing rocks and those stratigraphically near them, with two objects in view: first, of fixing the age of the coal beds, and second, of correlating the formations of the great coal fields on opposite sides of the mountains by means of the data from these small fields intervening between them.

Monument Creek Group and its Relations to the Denver and Arapahoe Formations: G. B. RICHARDSON.

The Monument Creek Group, Hayden's name for several thousand feet of arkosic deposits on the Platte-Arkansas divide in Colorado, is separated into two parts on the basis of a well-marked unconformity. The rocks above the break carry titanotherium bones of Oligocene age, and the rocks below contain leaves of Eocene age. The

lower parts of these lower deposits strike into the Arapahoe and Denver formations of the Denver Basin, and it appears that those formations are equivalent to part of the lower division of the "Monument Creek."

Dark Scale of Hardness: ALFRED C. LANE.

The hardness of a mineral is its resistance to shearing stress. Like other properties of minerals, it may differ in different directions. When two similar surfaces are rubbed together, the softer mineral leaves a powder (streak) on the other. In order to be sure which mineral gives the streak, it is at times convenient to have besides the common Mohs scale of hardness, composed of light minerals, a "dark scale of hardness" of minerals whose color and streak is dark, especially in teaching. For such minerals, the following properties are desirable: quickly recognizable, easily obtainable, hardness uniform. The following minerals have been used by the writer: (1) graphite, with 1 good cleavage, at one extreme in the white scale, at the other extreme in the black; (2) stibnite (Sb_2S_3), with 2 good cleavages, bladed; (3) galenite (PbS_2), with 3 good cleavages; (4) iron (use soft wire nail), magnetic, ductile; (5) niccolite (NiAs), characteristic color, no cleavage; (6) magnetite (Fe_3O_4), magnetic, brittle. The minerals mentioned seem fairly satisfactory. Above six, the author does not know whether spinel or some other mineral would be more desirable, but as there are comparatively few minerals concerned, it is not important.

Demonstration of Relative Refraction: ALFRED C. LANE.

The method of determining relative index of refraction developed by Exner, Becker and Schroeder van der Kolk¹ may be demonstrated to a class as follows: A large beaker of water placed just a little to one side of a window or other source of light will show a bright streak on the farther side, having a higher index than the surrounding medium. A test tube full of air placed in the beaker will show a bright streak of total reflection on the nearer side, the air within having a smaller index than the surrounding medium.

A Stratigraphic Study of the Appalachian and Central States with Reference to the Occurrence of Oil and Gas: GEO. H. ASHLEY.

It has always been supposed by the oil and gas men that the Appalachian region, extending from Pennsylvania to Alabama, was a stratigraphic

unit, and it has been a mystery that eastern Kentucky, Tennessee and Alabama should not yield as much oil and gas as Pennsylvania or West Virginia. The mystery largely disappears when a comparative study is made of the stratigraphy of the Appalachians as a whole. The paper compares graphically the stratigraphy of the southern and northern Appalachians and the central states with reference to the occurrence of oil and gas.

The paper was discussed by H. B. Kummel.

Granularity Limits in Petrographic-microscopic Work: FRED E. WRIGHT.

In this paper the petrographic microscope is treated as a measuring device for the exact determination of the optical properties of crystal plates, especially of minute crystal fragments and of crystallites. The methods now available for the purpose are considered briefly with special reference to their accuracy and applicability to the investigation of fine-grained silicate preparations. Attention is directed in particular to the lower granularity limits at which satisfactory measurements of the different optical properties of a mineral grain can still be made.

The Arkansas Diamond-bearing Peridotite Area: L. C. GLENN.

Evidence will be offered of the circulation of presumably thermal waters about the margin of the original pipe described by Branner. A supposed extension of the peridotite area proves to consist of disintegrated peridotite mixed intimately with well-rounded quartz sand and occasional water-worn chert pebbles and was evidently water-laid. Indications of the age of this material will be given, narrowing down the period within which the extrusion of the peridotite must have occurred.

The paper was discussed by A. H. Purdue.

Resins in Paleozoic Coals: DAVID WHITE.

Resins are present in most coals, except possibly those of the highest grades, the amount depending in general on the degree of concentration (residual) resulting from the decay and reduction of the attending plant structures. Interesting examples of megascopic resins in coals from the Carboniferous of the Mississippi Valley and Montana indicate the presence of resin in the Paleozoic coals in proportions probably as large as in the coals of the Mesozoic and Tertiary.

Onyx Deposits in East Tennessee: C. H. GORDON.

The existence of onyx deposits in east Tennessee has been known for a long time, and attempts have been made at recurrent intervals to utilize the

¹ Report Michigan Geological Survey, Vol. VI., p. 154.

material. Thus far no success has attended these efforts, but with persistent frequency hopes are aroused over some new "find" and glowing announcements are made of the possibilities of this industry. The onyx found is of cave formation and for the most part represents the remnants of vanished caves. The character and extent of the deposits was discussed and the possibilities of their commercial development.

Variation of the Optic Angle of Gypsum with Temperature: EDWARD H. KRAUS.

By using an oil bath to determine the variation of the angle of the optic axes of gypsum at different temperatures it is found that gypsum is optically uniaxial at approximately 90° C. for sodium light. Although Mitscherlich observed in 1826 that this change takes place at about 92°, the values given later by Des Cloizeaux, and more recently by Tutton, both of whom used air baths, are from 15° to 26° too high. Nevertheless, Des Cloizeaux's value of 116° C. for red light is the one commonly quoted. By plotting the values of the apparent angles of the optic axes at various temperatures up to 132.5° C., it is easily seen that the angle changes most rapidly in the vicinity of the uniaxial point, that is, between 80° and 100°, and further, that one axis, as was pointed out by Naumann, changes its position more rapidly than the other.

Notes on the Paragenesis of the Zeolites: J. VOLNEY LEWIS.

Zeolites and other secondary minerals occur in the Newark igneous rocks of New Jersey: (1) in cavernous spaces in the ropy pahoehoe of the extrusive Watchung basalts; (2) in fault fissures and fault-breccia of both the basalts and the great intrusive sill (Palisades, Rocky Hill and Sourland Mountain); (3) less commonly in the ordinary joint cracks of both the extrusive and the intrusive types. The rocks are essentially the same in both chemical and mineral composition, consisting essentially of pyroxene and plagioclase feldspars, with quartz-bearing and olivine-bearing facies. The zeolites and related silicates are essentially combinations of the feldspathic elements and water, with the addition of fluorine in apophyllite and boron in datolite; the accompanying amphibole, biotite, chlorite, epidote, serpentine and talc are derivatives of the pyroxenes. Hypotheses of origin dependent on the action of meteoric waters are inapplicable on account of difficulties of circulation, deoxygenation and sources of fluorine and boron; on the other hand, contact metamorphism

by the intrusives has produced in the adjacent shales minerals into which fluorine and boron enter, presumably by emanation from the magma. Hence magmatic waters are regarded as the most probable agent in the formation of the zeolites and accompanying minerals.

The paper was discussed by A. C. Lane and F. R. Van Horn.

Peculiar Iron Ore from the Dunham Mine, Pennsylvania: W. S. BAYLEY.

No abstract received.

Glacial Deposits of the Continental Type in Alaska: R. S. TARR and LAWRENCE MARTIN.

The glaciation of the interior of Alaska forms a striking contrast with the coast, where glacial erosion forms predominate, the deposits being largely under water, except for (1) 1,600 square miles east of Yakutat Bay, (2) 16,000 square miles in the Cook Inlet-Susitna Valley region, and smaller areas. The interior, between the coast ranges and the Endicott-Rocky Mountain system, where the National Geographic Society's party made some studies in 1911, has extensive glacial deposits of the continental type, previously described in part by Russell, Brooks and others and similar to those of the United States. These include at least (a) 15,000 square miles in the Copper River basin, (b) 27,000 square miles in the Tanana and Kuskokwim valleys, (c) 17,000 square miles in the Yukon Flats, (d) several thousand square miles on the Upper Yukon region in Canada and smaller areas. The dominant material is outwash and this extends long distances outside the country actually glaciated. In places there is wind-blown loess associated with this. In some localities it is still being deposited, and in the Copper River basin it has been accumulating during the time required for the growth of six or seven generations of trees. There is also some till, but this is largely buried beneath outwash. Lake deposits, eskers, kames and buried vegetation are also found, but thus far no one has found drumlins. In thickness, some of these deposits rival those of the middle west, one instance being known of probably 800 feet of gravel, sand, etc., grading out from the mountains to less than 100 feet fifty miles away. The presence or absence of these drift deposits seems to be chiefly a matter of favorable topography and existing deglaciation, a process much like that formerly in progress in northeastern and central United States.

The paper was discussed by W. M. Davis, C. A. Davis and H. M. Eakin.

Glaciation in Northwestern Alaska: PHILIP S. SMITH.

In northwestern Alaska there are small existing glaciers and evidence of much greater alpine glaciers in the geologic past. The present communication aims to set forth some of the observations made by parties from the U. S. Geological Survey during the field season of 1910 and 1911 in the Kobuk and Noatak regions of northwestern Alaska, which bear on the glacial phenomena.

Pre-Wisconsin Glacial Drift in the Region of Glacier Park, Montana: WM. C. ALDEN.

Along the east front of the Rocky Mountains from Two Medicine Lake northward to the International Boundary, valleys of most of the streams issuing from the mountains are bordered on either side by high, flat-topped ridges, whose crests stand 800 to 1,600 feet above the adjacent valley bottoms with maximum elevations ranging from 5,800 to 6,400 feet above sea level. These high flat-topped ridges taken together have the appearance of being remnants of a continuous high-level plain bordering the base of the bold mountain front and they have been so interpreted by Salisbury, Calhoun, Willis and Finley. Examination of nine of these ridges, those adjacent to Two Medicine, Cut Bank, Boulder, Swift Current and Kennedy creeks, and St. Marys and Belly rivers, and of high benches at corresponding levels on the west side of Belly River, shows the massive ridges to be composed of Cretaceous shales and sandstones with a capping of glacial drift ranging in thickness from 100 to several hundred feet. Fresh scarps resulting from recent slumping afford excellent exposures of the typical glacial till containing abundant striated boulders. In several places much of the till is cemented to a hard tillite conglomerate. In some places, as in the type exposure of Willis's "Kennedy gravels," the material is coarse, sub-angular to rounded cobble-stone gravel composed principally of quartzite, but even here careful search yielded numerous striated pebbles. Striated pebbles and boulders were found on the extensive flat top of Milk River Ridge eight miles from the mountain front. The component material in all cases is derived from the mountains. During the last great epoch of glaciation, the glaciers extended down nearly all the intervening valleys, in some cases nearly filling them. Cut Bank Glacier spilled through sags in the crest of Milk River Ridge, and St. Marys Glacier laid its lateral moraine along the upper slope and lower part of

the crest of St. Marys Ridge, but in some places the high level drift rises above that of these valley glaciers and is quite distinct therefrom, though of similar lithological composition. The topographic relations, cementation and considerable amount of modification due to weathering indicate that the high level drift is much older than that in the valleys, and represents a distinct and earlier stage of glaciation separated from the Wisconsin by a long interval during which much erosion was accomplished. Although the relations have not yet been carefully studied, it appears that this older drift includes some at least of the "quartzite gravels" described by the authors cited above, and regarded as pre-Glacial and possibly, but not certainly, some of those described by Dawson and McConnell in southern Alberta and denominated "Albertian Drift."

The paper was discussed by W. W. Atwood and A. P. Coleman.

Some Glacial Deposits East of Cody, Wyoming, and their Relation to the Pleistocene Erosional History of the Rocky Mountain Region: WM. J. SINCLAIR.

Twelve miles east of Cody, Wyoming, in the Eocene badlands in the vicinity of McCulloch Peak, angular blocks of Paleozoic limestone occur at elevations of 6,000 feet above sea, either on the crests of narrow ridges separating deep valleys cut in the badland clays or on terraces several hundred feet above the Shoshone River. No other rocks than limestone have been seen in these high level deposits, but at lower levels abundant pebbles and boulders of andesite may be found, all of which are water worn, while the high level material is highly angular, the only sign of abrasion being the pitted surface produced by the solvent action of rain water. Corals and bryozoa frequently appear in relief on the rain-etched surfaces. Individual fragments vary in size from a few inches or less to blocks $6 \times 8 \times 4$ or 5 feet. The source of the limestone is, undoubtedly, the Paleozoic formations of the mountains to the west of Cody. Glacial ice is the only known agent capable of transporting blocks of the size indicated. If they have been transported by ice, 1,200 feet or more of canyon cutting has intervened since their deposition, for they are stranded on narrow divides and comb ridges at least that high above the Shoshone River. If they are to be correlated with the first glacial advance in the Rocky Mountain region, much of the deep dissection of such intermontane troughs as the Bighorn Basin

must be regarded as an event of Pleistocene time.

The paper was discussed by W. W. Atwood and Wm. M. Davis.

Fossils of Lower Limestone of the Steep Rock Series: C. D. WALCOTT.

The paper described a new genus and two species of sponges found by Dr. A. C. Lawson in the limestone of the Steep Rock Series of Canada.

The paper was discussed by A. P. Coleman.

Evidence of Three Distinct Glacial Epochs in the San Juan Mountains of Colorado: WALLACE W. ATWOOD and KIRTLEY F. MATHER.

Abundant evidence of two distinct Glacial epochs has been reported by several investigators from various mountain ranges in the western portion of the continent. During the past season glacial deposits have been examined and mapped about the margin of the San Juan Mountains, which deposits have been interpreted to indicate an epoch of glaciation distinct from the two later epochs that have been clearly recognized in the history of the range.

For convenience, the three distinct epochs are referred to, beginning with the oldest as "San Juan," "Big Horn" and "Uinta."

The composition, distribution and topographic relations of the San Juan glacial drift indicate that this earliest known epoch was separated from the Big Horn Glacial epoch by a much longer time than the Big Horn was separated from the Uinta. The two later epochs appear to have been separated by a much longer time than has elapsed since the last disappearance of glacial ice from the range. The San Juan Glacial epoch is so far removed from the present time that the glacial deposits of that epoch are found at but a few places, where conditions were most favorable for their preservation.

There are reasons for believing that the San Juan Glacial epoch may have been characterized by small ice caps among the western ranges rather than by Alpine glaciers, which were the prevailing type during the Big Horn and Uinta epochs.

There are good reasons for believing that the San Juan epoch preceded the development of the great canyons among the mountains, and, therefore, that much of the sculpturing which has given form to the scenic features of the range is inter- and post-Glacial in origin. The time relation of the epochs of glaciation to other events in the physiographic history of the range were also suggested.

The paper was discussed by H. E. Gregory.

Glacial Investigations in Minnesota in 1911:

FRANK LEVERETT.

A sheet of old calcareous drift deposited by an ice sheet radiating from central Canada covers nearly all of Minnesota and extends into western Wisconsin. The prominent moraines of western Minnesota, named by Upham, Itasca, Leaf Hills and Fergus Falls, were formed in the order named, as is shown by the glacial drainage from them. The rock constituents of these moraines show remarkable disintegration that suggests a possible pre-Wisconsin age. After these moraines were formed by the ice radiating from central Canada, there followed an ice movement radiating from the high tableland northeast of Rainy Lake. This moved across the northern ends of the above-named moraines and extended a few miles beyond the portion of the Mississippi above St. Paul. This produced the so-called "red drift." After this ice movement waned there followed a readvance of the ice sheet radiating from central Canada which had its main axial movement through the Red-Minnesota-Des Moines Valley; but which also extended southeastward across the portion of the Mesabi Range west from Hibbing, Minnesota, and spread to the left and right in a basin which divides its drainage between the St. Louis and Mississippi Rivers. This ice movement deposited the so-called "gray drift" of the Minnesota Reports. It forms only a thin veneer on the portions of the Leaf Hills and Fergus Falls moraines which it overrode, and it failed to cover all of the Leaf Hills moraine. The correlative position of the Lake Superior Lobe is found to have been but little beyond the western end of the present lake, in Carleton County, Minnesota. A large glacial drainage line opened a great valley along the St. Louis between Floodwood and Carleton, but was there turned southwestward because of the presence of the Superior Lobe. The relations of this latest ice movement from central Canada to the Glacial Lake Agassiz are such as to make necessary a radically different interpretation from that given by Upham in his monograph on Lake Agassiz.

The paper was discussed by Lawrence Martin and J. B. Tyrrell.

Recent Studies of the Moraines of Ontario and Western New York: FRANK B. TAYLOR.

The paper was entirely descriptive of moraines recently mapped in the areas of Ontario and western New York.

Remarks were made by W. M. Davis and H. L. Fairchild.

A Grooved and Striated Contact Plane between the Nebraskan and Kansan Drifts: J. ERNEST CARMAN. (Introduced by George F. Kay.)

The paper described the unique feature of a grooved and striated contact plane between the Nebraskan (pre-Kansan) and Kansan drifts. Both sides of the contact plane are striated. Neither side is the mold of the other. The possible explanations are considered and the conclusion reached that glaciation produced the feature.

The Nebraskan Drift of the Little Sioux Valley in Northwest Iowa: J. ERNEST CARMAN. (Introduced by George F. Kay.)

The paper traced a farther extension of the Nebraskan drift and compared the Nebraskan and Aftonian deposits of this region with those along the Missouri River.

Dr. Carman's two papers were discussed by J. W. Spencer, F. Leverett and W. M. Davis.

Hanging Valleys and their pre-Glacial Equivalents in New York: J. W. SPENCER.

Visiting that most beautiful gorge, Watkins Glen, at the head of Seneca Lake, it would seem that the stream is entirely post-Glacial; but above the railway bridge a great cove, like that of the Whirlpool Basin at Niagara, is developed, with its northern side and end composed of drift. Its continuing channel to the lake has been discovered by boring. The same is true of other falls in this locality. Taughannock, on the western side of Cayuga Lake, is of little less importance. Its pre-Glacial channel, as observed by Hall in 1842, is situated immediately to the north.

Equally important are hanging valleys in northern New York. Between Carthage and Boonville is a plateau at 1,400 feet above sea level, overlooking the Black River and the much lower country east of it. The plain is bounded on the west by an escarpment 500 feet high, surmounted by another plateau. The Black River shales here are easily incised. Here the finest hanging valley with waterfalls is Whetstone Gulf, two miles north of Housie P. O., while the great pre-Glacial valley occurs at this hamlet, with the drift partly removed from it.

It seems that wherever an important drainage basin occurs with modern waterfalls, equivalent pre-Glacial valleys may be found, although more or less filled with drift. Accordingly, in New York State hanging valleys of themselves are no evidence whatsoever of the over-deepening of the trunk valleys or plains in front of them by glacial erosion.

Closing Phase of Glaciation in New York: H. L. FAIRCHILD.

As the Labradorian ice sheet melted away from the north border of New York State, it allowed the water of the ice-bound Lake Iroquois to escape at Covey Hill Gulf and to pass around the northeast slope of the Adirondack highland. Being confined and directed by the ice border, this stream flow produced the extensive areas of bare rock in the towns of Mooers, Altona and Beekmantown, formerly described by Woodworth (N. Y. State Museum Bulls., 83, 84). The later stream flow, along the Altona rocks, determined the level of a narrow lake lying northwestward, into which Lake Iroquois was lowered by the waning of the ice front on Covey Hill, and for a time this lake succeeded Iroquois in the Ontario basin. It is proposed to call this water Lake Emmons (after Ebenezer Emmons, whose district in the first geologic survey of the state covered this area). The further weakening of the ice border finally allowed Lake Vermont (named by Woodworth), which had previously been confined to the Champlain Valley, to succeed Lake Emmons and in turn to occupy the Ontario basin. It is proposed to call this expanded water Lake Vermont-New York. These two water planes in the Ontario basin, inferior to Iroquois, are represented chiefly by delta sand-plains on the larger streams. Eventually the waning of the ice east of the Champlain embayment allowed the glacial waters to become confluent with the sea, and the sea level waters were thus established in both the Champlain and Ontario basins at the same time. The height of the marine beaches about Covey Hill is 525 feet, which definitely gives the amount of land uplift on the international boundary since the ocean transgressed that area. Maps exhibit the glacial drainage channels, the deltas and the shore lines of the three water planes in the Champlain district and the four planes in the Ontario district.

The paper was discussed by F. B. Taylor, J. W. Spencer and H. L. Fairchild.

Post-Glacial Erosion and Oxidation: GEORGE FREDERICK WRIGHT.

(1) Opportunities for observation in Ohio. (2) Small amount of erosion by the streams north of the watershed entering Lake Erie. (3) Esker terraces in the valleys of the Styx and Killbuck on the south side of the watershed. (4) Comparison of calculations from these sources with those from Niagara and other post-Glacial gorges. (5) Ex-

tent of pre-Glacial oxidation. (6) Evidence of small amount of oxidation since the Wisconsin epoch. (7) Evidence that the till of the earlier Glacial epoch consists largely of material oxidized during pre-Glacial times. (8) Evidence of unoxidized material mingled with the highly oxidized material of the earlier epoch. (9) Evidence indicates that the date of the Wisconsin epoch is to be reckoned by thousands, rather than by tens of thousands of years, and the earlier epochs by tens of thousands rather than by hundreds of thousands of years.

The paper was discussed by F. Leverett, J. W. Spencer, H. L. Fairchild and the author.

The Intermingling of Pleistocene Formations: B. SHIMEK.

The paper discussed the effect produced by ice-sheets passing over older Pleistocene formations. Special illustrations are found in the mingling of fossiliferous loess and Wisconsin drift at Des Moines, Iowa, fossiliferous silts at Sioux Falls, S. D., and in other places.

Loess a Lithological Term: B. SHIMEK.

The term "loess" has commonly been understood as implying a more or less distinct division of time. The fact is set forth that there are several loesses deposited at different periods and that loess does not designate a distinct period of time, but indicates rather a condition of deposition, as do such terms as "sandstone," "limestone" and "drift."

Professor Shimek's two papers were discussed by W. C. Alden, F. V. Emerson, Frank Leverett, G. F. Wright and the author.

Criteria for the Recognition of Ancient Delta Deposits: JOSEPH BARRELL.

Previous to the discussion of criteria, definitions were given and an analysis of the parts of a delta. The criteria naturally are different for each part. Variations in the proportions of the parts, the ratios in which these may enter into ancient formations and the intergradations of parts were next considered. Where the conditions of delta growth were such as to give gradations between parts, the criteria become overlapped and tend to result in confusion. It is concluded that deltas of previous geologic ages have commonly developed under quite different conditions from those taken as typical in modern deltas. The principle of a delta cycle is next developed, showing the theoretic stages of rivers building outward and upward against the sea, followed in a later stage by marine dominance

and plantation. Where the larger features of an ancient deposit are known, the principle of the delta cycle may be of value as a criterion of origin. Illustration is made by application to the late Mesozoic formations of the Atlantic Coastal Plain. The evaluation of stratigraphic criteria is next taken up with the view first of separating the sub-aerial delta beds—those periodically exposed to the air, from the subaqueous—those permanently covered with water. Secondly, however, the criteria record also physiographic and climatic conditions controlling the character of the beds. The stratigraphic criteria are taken up in order, and the degree of significance attaching to each is discussed. Two chief conclusions are reached. First, the need of extended study of the stratigraphic characters of present sedimentation. Second, most individual criteria are to some degree indeterminate and a conclusion in regard to the mode of origin of a formation or part of a formation should, in order to obtain acceptance, be based on the convergence of several lines of evidence.

Stratigraphic and Paleontologic Features of Ancient Delta Deposits: A. W. GRABAU.

After a brief reference to the pre-Cambrian or early Cambrian delta fan of the Pacific Province and the Torridon of Scotland, the author discussed the late Ordovician and early Silurian fans of the Appalachian region, the Schawangunk dry delta fan and its relationship to the Salina desert, the Esopus delta and its relation to the Oriskany deposits, the Early Devonian talus breccia of Michigan and western Ontario, the Old Red of Scotland and the Catskill group, the Pocono, Mauch Chunk and Pottsville and the Triassic fans of America and western Europe, with special reference to their stratigraphic and paleontologic characters and their bearing on paleogeography.

A Mississippian Delta in the Northern New River District of Virginia: E. B. BRANSON.

A delta started in the Devonian in the New River district and continued through most of the Mississippian. The thickness of the Mississippian part is more than 5,000 feet and consists of varicolored shales and sandstones that thin out in all directions excepting southeast from this region. The Mississippian rocks are known as the Pulaski formation and are to be correlated with the Pulaski, Greenbrier, Bluefield and Hinton formations fifteen miles farther north.

Discussion of the last three papers was participated in by J. M. Clarke, David White, G. W.

Stose, A. Keith, G. I. Adams, E. T. Wherry, H. B. Kümmel and W. C. Alden, with replies by Joseph Barrell and A. W. Grabau.

Differential Erosion and Equiplanation in Portions of Yukon and Alaska: DELORNE D. CAIRNES. (Introduced by Percy E. Raymond.)

Certain limestones and dolomites have been found to offer much greater resistance to ordinary sub-aerial erosive agencies than most other types of sediments, although many of these may be considerably harder and apparently better adapted to withstand the destructive forces to which rocks are exposed. In portions of the Yukon plateau province, the original peneplanated upland surface has been almost entirely destroyed in areas in which the bed rock is chiefly highly metamorphosed slate and quartzite, but is well preserved in adjoining tracts where limestones and dolomites predominate.

Where remnants of the original plateau-surface remain, agencies, including nivation, frost and chemical action are at work on the upland tending to remove all inequalities of the surface by transporting material from the upper to the adjoining lower levels; for this process the term "equiplanation" is proposed. This name has suggested itself as its results tend to make the elevation of all points equal in the area affected. Equiplanation is the reverse of peneplanation, as by isoplanation there is but a slight if any loss of material within the planated areas, but in peneplanated tracts all crustal matter above sea-level tends to become transported to the ocean. Equiplanation thus includes all planating activities, even wind action, whereby a plain-like surface tends to be produced, and by which there is no perceptible loss of material to the planated tract; all ordinary stream action, which is the main factor in peneplanation, is thus excluded.

The paper was discussed by W. W. Atwood, W. M. Davis, H. M. Eakin and the author.

The Cenozoic History of the Wind River Mountains, Wyoming: L. G. WESTGATE and E. B. BRANSON.

A preliminary account of the successive peneplanes, partial peneplanes and terraces of the southern part of the Wind River Mountains, the pre-glacial gravels capping some of the terraces and the relation of the terraces to deposits of an earlier and a later glaciation.

The Stability of the Atlantic Coast: DOUGLAS WILSON JOHNSON.

The results of the Shaler Memorial investigation of shoreline changes along the Atlantic coast

indicate that there has been no appreciable subsidence of this coast within the last few thousand years. The phenomena which seem to indicate recent subsidence appear to fall into three groups:

(1) Fictitious appearances of subsidence which are produced by wave action on a retrograding shore line without any change in the level of land or sea; to this group belong many instances of submerged stumps, peat exposed at low water on the seaward side of barrier beaches, erect trees recently killed by the invasion of salt water, etc. (2) Phenomena produced by a local rise in the high tide surface, due to a local change in the form of the shoreline, unaccompanied by any general change in the relative level of land and sea; in this group may be found examples of practically all phenomena ordinarily attributed to a recent subsidence of the land. (3) Phenomena produced by an actual subsidence of the land or rise of the sea level which occurred some thousands of years ago; in this group belong many of the deeply buried peat deposits and submerged stumps. The evidence of coastal stability consists of (1) the form and position of successive beach ridges the oldest of which were built by the waves thousands of years ago, yet later than the deeply buried peat deposits; (2) the position of abandoned marine cliffs on which the waves can not have worked in recent time; and (3) the absence of a fringe of dead trees on those portions of the coast which are exposed neither to direct wave attack nor to local fluctuations of the high tide surface. It is concluded, with reference to the Atlantic coast, that the land can not have subsided as much as a foot within the last century; that there can have been no long-continued progressive subsidence at so high a rate as one foot per century, within the last few thousand years; and that no evidence thus far available can be regarded as satisfactory proof of any degree of recent subsidence, either spasmodic or progressive.

The paper was discussed by C. A. Davis, H. B. Kümmel, J. W. Spencer and A. C. Lane.

Physiography of the East African Plateau: GEORGE L. COLLIE.

Four physiographic regions may be recognized in British East Africa. First, the coastal plain; second, the foot plateau; third, the gneiss plateau; fourth, the lava plateau, which includes within its boundaries the great Rift Valley. The coastal plain is generally but two or three miles wide. It is composed of recent coral rock, and it is a true degradation plain; the agent is probably marine

erosion. Rising rather abruptly from the coastal plain is the great plateau which extends to the basin of Victoria Nyanza. The frontal portion, called by Gregory the foot plateau, is underlain by sedimentaries of Mesozoic age. The main portion of the plateau is gneiss, but toward its western border there have been great extravasations of lava, which have completely covered the original gneiss surfaces over a belt 100 miles wide and extending north and south indefinitely. The lava flows are connected with the rifting processes that have formed the rift valley. The underlying rocks have some bearing upon the minor features of the different regions, but this is a matter of detail. The plateau as a whole from ocean to the Victoria Nyanza basin should be considered as a unit in its larger aspects. The plateau is a very ancient feature; it has been thoroughly peneplaned, though great residual masses of gneiss remain, especially in the region between Voi and Kiu. These mound rocks in some cases rise to the dignity of mountain ranges. The most remarkable feature of the plateau is the constant, uniform rise of the peneplaned surface from sea level to a height of nearly 10,000 feet at the Mau or western escarpment of the Rift Valley. The plateau surface is really a great beveled slope which rises on the average about 20 feet to the mile for 500 miles. The plateau is typical of those that lie in the monsoon region, in that only the higher portions and those that lie near sea level are being acted upon by normal erosion. The intermediate and by far the greater area is being degraded by deflation and sheet-flood erosion, chiefly. There are two brief and widely separated rainy seasons. The conditions are such that, in the main, there is a large intake of ground water and relatively little run off, and hence very little dissection. In the interim between rainy seasons the ground becomes parched and dry, so that deflation becomes of importance and offsets dissection. The plateau confirms the truth of observations made in South Africa and elsewhere that one type of peneplanation may go on at any altitude above sea level. This type of peneplanation does not require desert conditions, as is sometimes said. Thirty inches of water fall annually over much of this plateau, but it does not require monsoon conditions where rainfall is concentrated in widely separated rainy seasons with arid or semi-arid conditions in between.

On the Nomenclature of Faults: HARRY FIELDING REID.

This was a preliminary report by the chairman of the committee appointed by the society at the Baltimore meeting (1908) and was submitted for discussion and criticism in advance of making a final report at the next meeting of the society.

Boulder Beds of the Caney Shale at Talahina, Oklahoma: J. B. WOODWORTH.

The Caney shales of Mississippian age in southeastern Oklahoma carry grooved and striated stones and large boulders, all of which phenomena have been described by Mr. J. A. Taff, of the Geological Survey. The writer describes the best known locality near Talahina, Okla., and ascribes the markings on the stones and boulders to internal rock movements accompanying the faulting of the beds. It is thought with Mr. Taff that the distribution of the boulders, aside from the nature of their striated surfaces, demands transportation by ice. Other evidence is briefly cited in support of the idea that the Permian Glacial period was preceded by signs of widely distributed ice action of one kind or another in the Carboniferous period in the northern hemisphere.

Some Coastal Marshes South of Cape Cod:

CHARLES A. DAVIS.

A report on a continuation of the work on salt marshes in the vicinity of Boston, the results of which were reported at the Boston meeting of 1909. The structure of salt and brackish marshes on the south side of Cape Cod and on Long Island was described and the bearing of this on the problem of recent coastal subsidence was discussed.

The paper was discussed by J. B. Woodworth, A. W. Grabau and the author.

Structure of the Helderberg Front: A. W. GRABAU.

The Helderberg Front is the northern extension of the westernmost belt of the Appalachian folded area, left after extensive erosion. The former extent east of the Hudson is partly indicated by Becraft Mountain and Mt. Ida. The basal part is of folded Hudson strata unconformably succeeded by late Silurian showing various phases of overlap. The Appalachian folds are of the usual asymmetric type, while the range from near Rosendale to Catskill and beyond is complicated by one or more pronounced overthrusts. The first of these was described by the author from Kingston and subsequently more fully discussed by Van Ingen and Clark. Chadwick has described a part of the thrust at Saugerties, and the author has determined its character near Catskill. Several new sections from this last region were presented.

The paper was discussed by J. B. Woodworth.

Some Relations between Gravity Anomalies and the Geologic Formation in the United States: WILLIAM BOWIE. (Introduced by A. H. Brooks.)

A report of an investigation of topography and its isostatic compensation upon the intensity of gravity will soon appear as a Coast and Geodetic publication. This and a subsequent investigation, involving 124 gravity stations, show the gravity anomalies in the United States are very small as a rule and that there is no apparent relation between the size and sign of the anomalies and the character of the topography. There is, however, a relation between the sign of the anomalies and the geologic formation. The stations in the older formations tend to have anomalies of the positive sign, indicating an excess of mass, and the stations in the most recent formations tend to have anomalies with the negative sign. It is probable that the anomalies are caused by erroneous assumptions regarding the surface density of the material at a station, and to a departure of the crust of the earth near the station from a state of complete isostatic compensation.

The paper was discussed by H. F. Reid and the author.

The following papers were presented by title:

Geological Reconnaissance in Northeastern Nicaragua: OSCAR H. HERSHEY.

The Geology of Steep Rock Lake: ANDREW C. LAWSON.

The Mesozoic Stratigraphy of Alaska: G. C. MARTIN.

Color Scheme for Crystal Models: GEORGE H. CHADWICK.

Occurrence of Petroleum Associated with Faults and Dikes: FREDERICK G. CLAPP.

New Minerals from the Fajas of Brazil: OLIVER C. FARRINGTON.

Progress of Opinion as to the Origin of the Iron Ores of the Lake Superior Region: N. H. WINCHELL.

Saponite, Thalite, Greencalite and Greenstone: N. H. WINCHELL.

Pre-Wisconsin Channels in Southeastern South Dakota and Northeastern Nebraska: J. E. TODD.

Geographic Cycle in an Arid Climate: Should its Development be by Wind or Water? CHARLES R. KEYES.

The Effect of Rapid Off-shore Deepening on Lake Shore Deposits: RUFUS MATHER BAGG, JR.

List of Underground Temperatures in the United States: N. H. DARTON.

A Bibliography of the Mammoth Cave: HORACE C. HOVEY and R. ELLSWORTH CALL.

The following officers were elected for 1912:

President—Herman LeRoy Fairchild, Rochester, N. Y.

First Vice-president—Israel C. White, Morgantown, W. Va.

Second Vice-president—David White, Washington, D. C.

Secretary—Edmund Otis Hovey, New York, N. Y.

Treasurer—William Bullock Clark, Baltimore, Md.

Editor—J. Stanley-Brown, Cold Spring Harbor, N. Y.

Librarian—H. P. Cushing, Cleveland, Ohio.

Councilors (1912-14)—S. W. Beyer, Ames, Iowa, and Arthur Keith, Washington, D. C.

Fellows elected December 28, 1911: R. C. Allen, Robert Van Vleck Anderson, Manley Benson Baker, Edwin Bayer Branson, Durdon Montague Butler, Stephen Reid Capps, Jr., George Halcott Chadwick, Clarence Norman Fenner, James H. Gardner, Walter Granger, John Sharshall Grasty, William Otis Hotchkiss, Cyril Workman Knight, Adolph Knopf, Lawrence Morris Lambe, Elwood S. Moore, Daniel Webster Ohern, Sidney Paige, Joseph E. Pogue, William Frederick Prouty, Elmer S. Riggs, Jesse Perry Rowe, John Joseph Rutledge, Joseph Theophilus Singewald, Jr., Burnett Smith, Frank Springer, Clinton Raymond Stauffer, Lloyd William Stephenson and Mayville William Twitchell.

Wednesday evening the Geological Society of America joined with other affiliated societies and the general American Association for the Advancement of Science in listening to the address of welcome by President Taft. Thursday afternoon was devoted to visiting the Geophysical Laboratory of the Carnegie Institution, while the evening was occupied with the annual dinner of the society followed by much speech making under the leadership of Dr. J. M. Clarke, of Albany, N. Y. On Friday evening, the presidential address of Professor Davis was followed by a smoker at the Cosmos Club tendered by the Geological Society of Washington to the Geological Society of America, the Paleontological Society and the Association of American Geographers.

The next meeting of the society will be held at Yale University, New Haven, Conn., a year hence.

EDMUND OTIS HOVEY,
Secretary

A HUNDRED years ago, when Gall and Spurzheim published the results of their work, the anatomy of the brain was poorly understood, and the explanations of the relation of its parts, or of the relation of the brain as a whole, to mental states and processes, were interwoven with absurd fancies or with quibbling speculations. There were many guesses postulating definite functions for large areas or divisions of the brain. The assumptions and suppositions were combated and defended mainly by logical methods, and, because of religious and other *a priori* views, direct observation and experimental methods took a subordinate position. What was lacking to make one or another of the various views acceptable was a series or collection of vitalizing facts that could be utilized or adduced in its support. The importance of the cerebellum was magnified by some; it was believed to be the seat of memory, or that of the so-called higher intellectual faculties. The basal ganglia were also thought by others to be concerned with the intellectual processes, whether as the structures or storehouses in which memories were collected or as the element involved in the processes of thought. Even the ventricles had been suspected of being the seat of certain intellectual functions, although it is probable that this view had no direct adherents at the time Gall began his investigations.

The foundation for Gall's work and teaching has been laid by Reil and others

MSS. intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹Address by the president of the Southern Society for Philosophy and Psychology, Washington, December 28, 1911.

who had previously taught the supremacy of the brain itself, and who had regretted the lack of knowledge of the anatomy of this important viscus. In support of their views, a few observations could be cited of patients who had lost particular functions, such as sensations, or the ability to move or to speak, when the brain was injured. The associations of these losses with brain injuries had rightly led some to believe that the brain is an organ with diversified functions. Many of the adherents to this view held, however, "that one can not explain the loss of certain intellectual faculties in certain cases except by admitting that the brain is composed of many partial organs," and also that "the smallest parts of the brain have special functions."

Gall, as he remarks in the preface to the work on the "Anatomy and Physiology of the Nervous System," had made numerous observations of the relation of facial, cranial and mental characteristics, and the hypothesis of diversified functions for different brain areas well fitted his own views. This was the origin of physiognomy and of phrenology. The mind, it was supposed, is composed of a collection of units, of mental states or faculties which differ from one another in degree or in kind. It was presumed, therefore, that some localized part of the brain was concerned with each of these supposedly different states and processes, and, consequently, it was believed that it should be possible to find definite brain centers which are associated with, or which produce by their activity, different mental processes. Thus was born a definite conception of centers in the brain for particular mental acts. This conception was naïve and crude, to be sure, but it is the one which has dominated neurology and nervous physiology for the past century,

and which is still to be recognized in present-day teaching and writing.

This view led to various attacks and defences, bombardments and counter attacks, which were usually futile in advancing the knowledge of the relations which were discussed but which were indirectly of the greatest value in the advance toward a better understanding of the relation of clinical phenomena to brain lesions. The discussions led to observations and to careful comparisons of material so that the doctrine of exact localization of centers was not new at the time that Broca startled the neurological world with the report of the relation of a definite brain lesion with the loss of the ability to speak.

The rigid localizations of Gall and the vagaries of Spurzheim and his imitators were not received with entire confidence and faith, but the conception of one function for one part of the brain was too simple and too alluring to be dispensed with. Instead of the general formula that the brain is the organ of mind, divisions were introduced and both the brain and the mind were fractioned. Observations of other aphasic conditions with concomitant cerebral lesions were recorded and the strict localization view continued to be dominant. Wernicke and his disciples stood on the platform with Gall, and discussed learnedly of concept and percept centers and centers for motor images in the cerebral cortex. It was supposed that the recently announced discovery of Fritsch and Hitzig afforded evidence of this for the motor sphere and the precise localization in the cortex of definite centers for sensory processes by various physiologists made many certain that the hypotheses underlying phrenology were correct. All were compelled to admit the principle of cortical cerebral localization, but the meaning of localization proved to be an apple

of discord (*e. g.*, the discussions between Munk, Goltz, *et al.*).

There were some who disputed the functional dismemberment of the brain, and withstood the establishment of spatial localizations for definite mental functions, but their voices were not listened to or their facts were denied, or their arguments disregarded. They contended that the clinical and physiological facts gave no warrant for a localization in parts of the cerebral cortex of mental functions as such, and furthermore they pointed out that the cortical centers did not operate independently, and that functions could not be considered apart from the totality of the elements involved.

The schematism of phrenology was, however, too alluring; it gave a definiteness to diagnosis, and it satisfied certain other practical and theoretical desires. Criticisms of this view from the psychological standpoint were laid aside, but since many of the clinical facts could not be fitted to the anatomical divisions, other evidence was sought. The myelogenetic studies of Flechsig were hailed as witnesses to support the contention of the anatomical localizations of mental processes. The developmental differences of Flechsig's fields (now forty in number) of the cerebral cortex were received with gladness, and were used as additional splints and crutches for the doctrine. But even this was not sufficient. Anatomical localization of the mental faculties could not be made certain without additional support and it is within the past few years that our latest contributions to the doctrine of phrenology have appeared. These may be described in brief as the histological localizations of mental processes.

It was discovered that certain areas of the cerebrum differ both macroscopically and microscopically from other areas, and

the careful examinations of the cerebrum led to the division of the cortex into a number of areas, which were considered by the observers to be quite distinct from one another.

Elliott Smith made a careful examination of the naked eye appearances of all regions of the cerebral cortex and found that the streaks of light and shade differed in parts. The conclusion was drawn that these appearances indicated differences in the arrangement of cells or fibers in the cortex and that the cerebral cortex could, consequently, be divided into these anatomically distinct areas. Campbell and Brodmann used finer methods, those of histology, and discovered that the cerebral cortex could be divided into areas, which had the cells collected in different groups, or which had different sizes of cells, or which had the fibers arranged in characteristic ways. Depending upon the methods which are used, the number of these histologically and macroscopically distinct areas varies from about eighteen to fifty. It does not appear to make much difference that the histologists are not in accord in regard to the number of the histologically distinct areas, or in their exact individual location, the important point appears to be that certain areas are anatomically distinct, sufficiently so, that they may be recognized by their histological and gross appearances.

These areas, because of their differences in structure, are supposed to have different functions. Brodmann has given the clearest pronouncement regarding the supposed functional value of these observations. He has written: "physiologically unlike parts have unlike structure," and "parts of organs which differ structurally must have different functions."

In these statements we have the entering wedge for a more complete phrenology than has been advocated since the time of

Gall. If each of these areas, histologically distinct from one another, has an individual function distinct from the functions of the other areas, we should also have a similar number of mental functions or faculties to correlate with them. Unfortunately for our purpose, the histologists have not attempted to give us the mental correlates of all the anatomically distinct areas, although in a few cases the anatomical reasoning and connections have led to certain psychological suppositions. It is in this way that we must account for the psychic areas of Campbell, and for some of the other psychological localizations which have been made.

An example of this anatomical reasoning is that of Campbell regarding the distribution of the sensory areas. In areas which were believed, because of the physiological and clinical evidence, to have sensory functions, Campbell observed that certain fibers "pursue a curious oblique course" different from other fibers in other neighboring areas. On the basis of this fact Campbell constructed other sensory areas, these latter areas being endowed by him with mental (*i. e.*, sensory) functions because in this one particular they had an appearance similar to that in supposedly known sensory fields. It did not appear to make any difference that these areas might have other well-marked differences. The main anatomical point is that these oblique fibers were discovered in different regions, and the important psychological point is that these minor similarities have been interpreted as indications of similarity of function of a mental order. In this case, Gall has been surpassed, and his phrenological reasoning outstripped.

The designation by Campbell of psychic areas, surrounding the so-called sensory areas, are interpretations of a phrenological nature of a supposed functional con-

nection of the primary receptive areas with these and of a relation of these areas to mental processes. In this there is a distinct psychological interpretation that the nervous impulses which start from the sense organs reach a part of the cerebral cortex and give rise to sensations, and that other nerve currents are sent to neighboring areas and give rise to perceptions.

Let us glance for a moment at the cortical area posterior to the fissure of Rolando. Campbell divided this region into two distinct zones (the postcentral and the intermediate postcentral) which are believed to be concerned with the afferent impulses from the skin and the underlying tissues. The zone bordering on the fissure, the postcentral, Campbell designates as "sensory," and that adjoining the first area "perceptive." In the first area the sensations of touch, of temperature, of pain and of movement are localized, and in the adjoining area (the intermediate postcentral) there are the psychic functions of localization of touches and also the so-called stereognostic sense. If we consider only the postcentral sensory area of Campbell, we might ask: Why should the same brain area be concerned with such unlike sensations as those which he attributes to it? By histological-phrenological reasoning we should have four, or even eight, distinct areas. Even though the gross sense organs have been differentiated, taste and smell, as sensations, are as much alike as are touch and pain and temperature and we might on anatomical grounds, if we closely follow Campbell, expect them to have seats in the same area. The observations of Cushing upon the effects of excitation of the postcentral area in conscious patients have not helped this attempt at a definite mental localization, and, in fact, they are decidedly opposed to it.

The motor area of the brain has been the

easiest for the anatomists to deal with, and it is the one to which they least often impute mental functions. In this connection, however, it is of interest to examine some of the evidence relating to this area to see how well its functions have been determined. In man this area is anterior to the fissure of Rolando, and is not simple. The cortex adjoining the fissure is to be differentiated from another anterior part and to these areas Campbell gives the names precentral and intermediate precentral. The primary part, that bordering upon the fissure, is the precentral, and this, according to Campbell, is bounded anteriorly by the other zone, which is physiologically connected with it. Stimulation of the cortex of the precentral area produces movements, and it has been a simple matter to explain the function by assuming that the cells govern the bodily musculature. But movement is also produced when the intermediate postcentral and other parts of the cortex are stimulated, and the latter movements are the more complex. In the precentral cortex the Betz cells are those to which the motor function has been imputed. These cells differ in number and in size in different parts of the precentral cortex, and these differences have been supposed to indicate functional differences, the use of the larger ones being variously interpreted as (a) indication of large movement, (b) of the extent of the nerve fiber or (c) of the number of muscle fibers which each controls. But differences in the sizes of these cells in the two hemispheres have been observed by Betz, and the larger size of those in the right hemisphere can not be explained in any of the ways that have been suggested. The Betz cells are reported to be absent in the guinea-pig, rabbit and rat, and we have no reason to suppose that these animals lack the ability to move or to coordinate

their movements. The recent studies have not usually been taken to suggest that the motor area is the seat or storehouse of motor memories, and in this respect there is a marked avoidance of a phrenological opportunity. Since the area is one of the most distinct histologically, and since it is one in connection with which extensive clinical and physiological observations have been made, it is of special interest that the histologists have been unable to explain in a satisfactory manner the reasons for the anatomical variations. Here, again, I would interpret the observations of Cushing and others on this area differently from Professor Pillsbury, who concludes that these results point to the non-mental function of this zone. We are not able to limit the localization of mental processes in this way, and, on the other hand, I do not believe that these observations can be interpreted as indications of a mental localization.

There are other facts which must be considered in relation to the localization of supposed mental functions in the motor area. The principal one is the phenomenon of nerve anastomosis. If two motor nerves are cut and the distal part of one be connected with the central part of another, and, conversely, the central part of the first be joined to the distal part of the second, there may be a return of function after a period of paralysis. We have no right to assume any anatomical alteration in the brain connections to account for this change, and the phenomenon has been interpreted, probably correctly, as a transfer of function. If this is to be interpreted in relation to any cerebral mental localization, it must surely be considered negative evidence.

In regard to some of the other so-called sensory fields we have almost as much information as regarding the one supposed

to be concerned with the sensations of touch, pain and temperature. Regarding the localization of mental states in these other areas, we have other suppositions which are to be believed as much as that regarding the mental functions of the post-central area. One of these, that the layers of the cortex in the so-called visuo-sensory sphere function to produce sensations of different color is a more bizarre supposition, and has even less clinical evidence in its support.

Many neurologists and some psychologists appear to believe that we have data which enable us to locate certain definite mental processes in parts of the cerebral cortex outside of the motor and sensory spheres. The disorders of speech, of the nature of aphasia, which are considered by some to be mental abnormalities, are due to localized injuries or destructions of parts of the brain. That the third frontal convolution, the area to which Broca assigned the function of motor speech, has a different structure than the surrounding regions, as has been contended by Brodmann, is a point made in favor of the localization of the speech function in this area. The criticisms of von Monakow and of Marie are, however, too trenchant to be disregarded, and the negative cases which they have cited are sufficient evidence that neither the mental processes connected with motor speech nor the supposed cortical speech mechanisms are definitely located in the part of the brain to which they were assigned by Broca, by Wernicke and by their followers.

One of the histologists has written: "It is unfortunate that we can not say that word deafness is invariably due to a lesion of the left superior temporal gyrus. Authentic cases have been recorded in which there has been no affection of this convolution and these, of course, increase our diffi-

culty in interpreting the condition." In another place he admits that the localization of this condition, even as a clinical phenomenon, rests upon only two cases which have been checked by careful post-mortem examination. Disregarding the number of cases which may properly be cited in support of the localization of this part of the speech function in this part of the cortex, it should be remembered that even one negative case is sufficient to demolish the whole structure of the mental speech function localization.

On the basis of the histological studies, we have also another kind of phrenological localization. This is a localization of particular processes of a mental order in certain layers of cells in the cortex. It will be remembered that the cortex is composed of rather distinct layers of cells with their fibers. Some histologists believe there are six layers, others five. Some of these layers have been disregarded in the formulation of the speculations. Bolton and Ariens Kappers believe that the layers have receptive and associative functions. Bolton disregards the first and fourth layers (he counts only five instead of six, as does Brodmann) and postulates the following functions for the other three layers: for the outer pyramidal layer he assumes a "psychic or associative function," for the third layer a receptive function, and for the fifth layer the function of lower voluntary and instinctive activity.

These facts indicate the general trend of the histological localization of function, and its tendency toward phrenology. What shall we say against this view or what shall be our attitude towards it? Brodmann assumes that the principle of localization has been settled, and all that needs to be done at present is to consider the "how" and "what" of localization. This view can not, however, be accepted.

It is the principle of localization which must be debated and settled. Whether it is the mental processes or cells which are localized is a matter which apparently the histologists and clinicians have not settled. It may be admitted that cells and cell groups are localized, and, although there is some doubt on the part of some clinicians, we may be willing to admit that certain symptoms are produced by definite lesions. We have, however, no evidence which will warrant the conclusion that mental states have been localized, and it is doubtful that many psychologists will believe in the crude histological localization of mental processes. The histological, the physiological and the clinical evidence warrants only a belief in the possibility of an association of brain lesions with motor, sensory and associational derangements, it does not warrant a belief in psychic localization.

Although it is apparent that mental states are not to be found spatially associated with definite areas distinguished from one another by histological and macroscopical characteristics, for practical purposes we must admit a close connection between the brain and mental processes. How then shall we conceive of the relation between the activities of the brain and mental states? The functions of the nervous cells, as functions, may include something which is at the basis of psychological states, but at the present time the physical and chemical activities of the cells can not be believed to be equivalents of the mental processes which may be concomitant with or the result of these activities. Since for practical purposes we may need some general principle of localization, we may say that mental processes are not due to the independent activities of individual parts of the brain, but to the activities of the brain as a whole. Here also I would not omit the cerebellum. It is well known that

similar mental processes may be inhibited by or may be lacking because of lesions in parts of the brain widely separated. This fact is the one at the basis of the diaschesis hypothesis of von Monakow. This hypothesis explains only certain clinical manifestations; it explains certain losses and how the same symptoms may be produced by diverse lesions. Conversely, it helps towards a proper understanding of the brain processes in connection with mental states. The individual parts of the brain do not work independently; they work interdependently, and it is because of the possible functional and anatomical connections that certain types or kinds of mental states are more in evidence than others. We should, on the physiological side, be not far wrong, if we compared the brain to a village or city as did Gregoire of Nice. There are paths and streets, definitely related to one another, but each independent to a certain extent. There are broad roads with many travelers, there are paths only occasionally traversed. There are houses from which the people come and to which they go; some pouring forth people in streams, others only occasionally; to some numerous people go and to others few. What goes on in the houses we can not tell. We can observe the "from" and the "where," the structure of the houses, and numerous other anatomical and histological facts, the effects of blocking of paths and streets and the destruction of houses, but the purposes of the travelers we do not know. We may have for the city a histological and a clinical localization, but this does not mean that we have also a mental localization.

From the anatomical and physiological standpoint, we deal solely with associations of an anatomical and physiological character. With these physiological associations mental processes are supposed to be

correlated. It is not necessary that we shall conclude that all of the mental processes are associational, and we must, in fact, admit that retention, and possibly other factors, in memory are not of this character. What memory means physiologically we do not know; where memories are stored we do not know; and how they are stored we do not know. All that we do know is that certain disturbances of the brain are accompanied by certain mental abnormalities, and that similar mental abnormalities are produced by or accompany diverse lesions. We have no facts which at present will enable us to locate the mental processes in the brain any better than they were located fifty years ago. That the mental processes may be due to cerebral activities we may believe, but with what anatomical elements the individual mental processes may be connected we do not know. Notwithstanding our ignorance, it would appear best and most scientific that we should not adhere to any of the phrenological systems, however scientific they may appear to be on the surface. We should be willing to stand with Brodmann, believing that mind is a function or an attribute of the brain as a whole, or is a concomitant of cerebral operations, but I at least am unwilling to stand with the histological localizationists on the ground of a special mental process for special cerebral areas or for special cerebral cell groups.

SHEPHERD IVORY FRANZ

GOVERNMENT HOSPITAL FOR THE INSANE

PROFESSORSHIPS IN CHINA

WE are requested to state that several teaching positions in the Imperial Pei-Yang University, Tientsin, China, are likely to be open as soon as stable conditions are restored in China. Applications should be sent to President S. H. Wang, Imperial Pei-Yang University, Tientsin. An application should contain: (1) a cable address so that the appli-

cant can be engaged by cable, if necessary, (2) a full statement of qualifications, especially practical and teaching experience, (3) age of applicant and other personal details, so that, in the absence of an interview some idea of the personality of the applicant can be obtained. The Imperial Pei-Yang University is the provincial University for Chih-li (the province which contains Peking), and its position in the educational system of China is similar to that which the state university of a correspondingly important state in the United States would occupy. This does not mean that it is comparable to the University of Wisconsin, for example. The university, founded in 1895 by Dr. Chas. D. Tenney, was destroyed in 1900 and rebuilt in 1902. Its present president is Wang Shoh-lien, a noted Chinese educator and man of affairs, a graduate of Woolwich, England. Of the numerous schools which are eventually to constitute the university only three have yet been organized, Law, Civil Engineering and Mining and Metallurgy. In 1910 the foreign staff consisted of two professors of law, three professors of civil engineering, one professor of mechanical engineering, a professor of history and economics, a professor of chemistry, a professor of mining and geology, and a professor of metallurgy, in addition to a numerous staff of Chinese professors and other officers. The courses of study in these schools are similar to those in American technical schools, but, as can readily be understood, the conditions surrounding the work are somewhat primitive, and make-shifts are often necessary. Nevertheless, Columbia University and the University of California have recognized the completion of the course in this university as equivalent to attaining the B.S. degree. A description of the university and its work can be found in *Engineering News* (one of the numbers during the autumn of 1910). All the work in technical subjects is done in English, though many of the students do not speak English with much ease or fluency. In some respects the equipment is quite complete, and in others it is lacking. The students are at

present comparatively few in number and in many cases their preparation is insufficient, but these disadvantages are being removed. The principal conditions of the contract which the university enters into with its professors provide for a three-year term of service. The salary is paid in silver at the rate of 300 Hongping taels per lunar month (the Hongping tael varies in value according to the rate of exchange, usually 60 cents to 65 cents; there are twelve and one third lunar months in the year). Free medical attendance is provided as well as suitable living quarters; these latter are substantial brick houses, provided with electric light and water. The traveling expenses of the professors to China and return are paid in the event of his completing his contract. The conditions of life in China are so different that it is impossible to convey an accurate idea of them in words. In general it may be said that any one who objects to unfamiliar and, in some respects, crude conditions of life and work would probably not enjoy the life in China, while others will find much of interest and pleasure in it. The cost of living is low, for \$1,500 per year a small family can live in much greater comfort than upon the same sum in America. It will be necessary for the applicant to sail from San Francisco during the first week in July, in order to begin work with the autumn term. More detailed information upon any points in doubt can be obtained by writing to Thos. T. Read, 420 Market Street, San Francisco, but any applicant should immediately send a letter containing the facts (1), (2), (3) to President Wang, stating, if necessary, that he is only tentatively a candidate, until fuller information is available. It must be remembered that the time available will not allow for many exchanges of letters and the final appointing will probably be done by cable. A copy of the application should be sent to Mr. Read.

SCIENTIFIC NOTES AND NEWS

It was proposed on behalf of the Royal Society and the Royal College of Surgeons that Lord Lister should be buried in West-

minster Abbey, and the consent of the dean was obtained. Lord Lister, however, had expressed a wish to be buried in Hampstead Churchyard, where the body of his wife lies. The first part of the funeral service was held in Westminster Abbey on February 16. Only members of the family were present at the interment in Hampstead Churchyard.

At the University of Pennsylvania exercises on Washington's birthday several honorary degrees were conferred, including the doctorate of laws on Dr. William J. Mayo, the surgeon; the doctorate of science on Carl Hering, the electrical engineer, and the doctorate of public hygiene on Dr. A. C. Abbott, professor in the university.

At the stated meeting of the committee on science and the arts of the Franklin Institute held on February 7 Elliott Cresson Medals were awarded as follows: Alexander Graham Bell, Sc.D., Ph.D., LL.D., of Washington, D. C., in recognition of the value of his solution of the problem of the electrical transmission of articulate speech. Samuel Wesley Stratton, D.Eng., Sc.D., of Washington, D.C., in recognition of his distinguished and directive work in physical science and metrology, and its application in the arts and industries. Albert A. Michelson, Sc.D., Ph.D., LL.D., of Chicago, Ill., in recognition of his original and fruitful investigations in the field of physical optics. Alfred Noble, C.E., LL.D., of New York, in recognition of his distinguished achievements in the field of civil engineering. Elihu Thomson, Sc.D., Ph.D., of Swampscott, Mass., in recognition of his leading and distinguished work in the industrial applications of electricity. Edward Williams Morley, Sc.D., Ph.D., LL.D., of West Hartford, Conn., in recognition of his important contributions to chemical science and particularly of his accurate determinations of fundamental magnitudes. Johann Friedrich Adolph von Baeyer, Ph.D., F.M.R.S., of Munich, Germany, in recognition of the many important results of his extended research in organic chemistry and of his discovery of synthetic processes of great industrial value.

Sir William Crookes, D.Sc., LL.D., F.R.S., O.M., of London, England, in recognition of his important discoveries in inorganic and analytical chemistry and of his pioneer work on the discharge of electricity through gases. Sir Henry Enfield Roscoe, Ph.D., LL.D., D.C.L., F.R.S., of London, England, in recognition of his extended and important researches in the domains of inorganic, physical and industrial chemistry.

SINCE Henry Shaw's death, in 1889, over \$400,000 has been paid in special street and sewer taxes and the like, for improvement of unproductive endowment property—two thirds as much has been spent in keeping up the grounds and plant houses and increasing the collection of plants at Shaw's Garden. This burden is now nearly lifted and income from the newly improved property as well as the full return from that which has always been productive is to become rapidly available for very large extensions and increased beautification of the garden. Carrying out the proposed improvements is expected so fully to occupy the time of the director that the trustees and Dr. Trelease, who has acted *ex officio* as a trustee for the last three years, are agreed that this development should be undertaken by a man who is free to give his entire effort to it, while the scientific work that Dr. Trelease has under way or in contemplation is sufficient to call for further freedom of his time from administrative encroachment. For these reasons Dr. Trelease, who has been director of the Missouri Botanical Garden since the death of its founder, in 1889, has asked to be relieved from the responsibilities of the office at the earliest convenience of the trustees, and intends, after this request has been granted, to give his entire time for the present to the completion and publication of a number of research papers on which he is now working, and which will involve study in the herbaria as well as at the St. Louis garden.

DR. GEORGE H. ASHLEY, state geologist of Tennessee, will resign to accept a position with the U. S. Geological Survey as a member

of the land classification board in charge of the coal work.

PROFESSOR MARSTON TAYLOR BOGERT, of Columbia University, has been appointed chairman of the American Commission on Organic Nomenclature, the other members of which are President Ira Remsen, of Johns Hopkins University; Professors W. A. Noyes, of the University of Illinois; T. B. Johnson, of Yale University; J. B. Tingle, of McMaster University; J. F. Norris, of Simmons College; M. Gomberg, of the University of Michigan, and Dr. C. S. Hudson, of the Bureau of Chemistry, U. S. Department of Agriculture. The commission will cooperate with similar national bodies in other countries in the revision of the nomenclature of organic compounds. The chairman will be glad to receive suggestions from American organic chemists.

PROFESSOR P. G. HOLDEN, head of the department of agricultural extension of Iowa State College, has resigned his position to engage in an active campaign for nomination for the governorship of Iowa on the Republican ticket. R. K. Bliss has been made acting head of the department.

DR. II. VON GROTH, professor of mineralogy at Munich, has been elected an honorary member of the London Chemical Society.

DR. F. W. DYSON, F.R.S., has been elected president of the Royal Astronomical Society.

PROFESSOR P. ANDOYER has been elected president of the French Mathematical Society.

PROFESSOR JOHN JOLY, F.R.S., has been appointed Huxley lecturer at Birmingham University for the current session.

DR. J. M. MCBRYDE, former president of the University of South Carolina, later president of the Virginia Polytechnic Institute, and now on the Carnegie Foundation, was awarded the McMaster medal by the University of South Carolina at the celebration of Founder's Day on January 12, 1912. The McMaster medal is awarded annually by the University of South Carolina to an alumnus or former student of the university for "distinguished service to mankind."

PROFESSOR RENÉ ZEILLER, the eminent paleobotanist of the Paris School of Mines and inspector general of mines, has been appointed president of the council general of mines, a public board under the Ministry of Public Works.

DR. W. WILIM, of the St. Petersburg Academy of Science, has been appointed director of the newly-established seismographic observatory at Pulkova.

MR. GEORGE H. CLAPP has been appointed to represent the Academy of Natural Sciences of Philadelphia on the occasion of the celebration of the one hundredth and twenty-fifth anniversary of the founding of the University of Pittsburgh. The council of the Société Géologique de France has appointed one of the foreign members of the society, Dr. C. R. Eastman, of the Carnegie Museum, to act as official representative of that body at the celebration.

A SMITHSONIAN expedition, under the direction of Mr. H. C. Raven, will start in a few days for eastern Dutch Borneo, where a collection of vertebrates and ethnological material will be made for the United States National Museum.

MR. WALDEMAR T. SCHALLER, chemist and mineralogist of the United States Geological Survey, is soon to leave Washington for a six-months' trip to Europe where he will visit the principal mineral collections and continue his studies at the universities of Heidelberg and Munich.

DR. WARREN D. SMITH, chief of the division of mines, Bureau of Science, Manila, will be on leave in the spring and summer of 1912 in the United States, making visits to the various laboratories in Washington and Pittsburgh. Later he will spend a month in one of the California oil fields investigating the geology and operations there.

PROFESSOR GEORGE D. HUBBARD, head of the department of geology in Oberlin College, is engaged in special research under the Ohio State Geological Survey, in the attempt to formulate some definite conclusions regard-

ing the problems of pre-glacial drainage in the Ohio Valley.

PROFESSOR WILHELM PASZKOWSKI, the director of the Scientific Information Bureau of the University of Berlin, will leave for the United States on March 9, to deliver a series of lectures on German culture on the invitation of the Germanic Society of New York. He is to lecture at Columbia, Harvard, Yale and other universities.

PROFESSOR CASPER RENÉ GREGORY, of the University of Leipzig, is giving a series of lectures at the University of Illinois on "The Development of Science in Germany." Dr. Gregory is the first American-born professor to receive appointment in a German university. He holds the chair of theology at Leipzig.

DR. HAVEN METCALF, of the U. S. Department of Agriculture, delivered on February 17 the John Lewis Russell lecture before the Massachusetts Horticultural Society. His subject was "Fungous Diseases of the Chestnut and Other Trees."

LECTURES have been given before the graduate students in highway engineering at Columbia University by Mr. Clifford Richardson, consulting engineer, New York City, on "Trinidad and Bernudez Asphalts and Their Use in Highway Construction"; by Mr. Nelson P. Lewis, chief engineer, Board of Estimate and Apportionment, New York City, on "Design of Highways and Systems of Highways," and by Mr. A. W. Dow, chemical and consulting paving engineer, New York City, on "The Inspection of Sheet Asphalt Pavements."

PROFESSOR ARTHUR KEITH, curator of the museum, began on February 26 a course of six lectures at the Royal College of Surgeons of England, on phases in the evolution of man.

ON February 24 Sir J. J. Thomson began a course of six lectures at the Royal Institution on "Molecular Physics."

CHARLES ROBERT SANGER, Ph.D., professor of chemistry and director of the chemical laboratory at Harvard University, died on February 25, at the age of fifty-two years.

THE REV. FRANCIS BASIFORTH, distinguished by his experiments in ballistics, formerly professor of applied mathematics at Woolwich, died on February 12, at ninety-three years of age.

M. JACOB AMSLER, corresponding member of the Paris Academy of Sciences in the section of mechanics, has died at the age of eighty-nine years.

THE New York State Civil Service Commission announces among other examinations that of medical superintendent at the Matteawan State Hospital for the Insane at a salary of \$3,000, with maintenance for the superintendent and his family, and of specialist in agricultural education at a salary of \$2,500.

THE Kaiser Wilhelm Foundation for the Advancement of Science has under consideration the establishment of a biological research institution.

MR. W. LEO BULLER has presented to the Dominion Museum, Wellington, New Zealand, a collection of about 700 Maori ethnological specimens which had been collected by his father, Sir Walter Buller.

ACCORDING to a note in *Nature* the possibility of the discovery of a remedy for cancer has been advanced a stage by the preparation of Professor Wassermann, of Berlin, of a substance which possesses a curative action experimentally on cancer of mice. Professor Wassermann reasoned that since the cancer-cells are growing rapidly, their oxygen requirements would be different from, and greater than, those of the cells of the body generally. He sought for some substance which might interfere with the oxygen supply to the cancer-cells, and finally adopted selenium as a means to do this. The next problem was to convey selenium to the cancer-cells by means of the blood stream, and after testing some hundreds of preparations a compound of selenium with an aniline dye eosin was found to fulfil this condition. If the eosin-selenium compound is injected into a healthy mouse it becomes pink all over, but if into a mouse with a cancerous tumor the tumor only becomes colored,

demonstrating the selective absorption of the substance. After two or three injections of the substance into a mouse the subject of cancerous tumors, the tumors are found to have softened, and after six to eight doses they become cystic, diminish in size and finally disappear, and no recurrence takes place. The eosin-selenium compound is, however, poisonous, and a certain number of mice succumb under the treatment. Moreover, only small tumors (up to the size of a cherry) are definitely cured; with larger tumors so much disturbance ensues that the animals die.

THE U. S. Bureau of Education has recently issued Bulletins Numbers 13 and 16 for 1911, the former containing the Report of the American Committees I. and II., on Mathematics in the Elementary Schools of the United States, and the latter containing the Report of the American Committees III. and IV., on Mathematics in the Public and Private Secondary Schools. These reports are prepared under the direction of the American commissioners of the International Commission on the Teaching of Mathematics. They may be secured by addressing the U. S. Commissioner of Education at Washington.

IN commemoration of the seventieth birthday of Professor J. J. Rein, January 27, 1905, the friends of this well-known German geographer instituted a fund, the yearly income of which should be devoted to the furtherance of geographical research. We learn from the *Geographical Journal* that the contributions made then and since to the fund reached, in November last, a total of nearly 9,000 marks, and in the same month the rules for the administration of the fund were drawn up. It is proposed, unless reason to the contrary should arise, to wait until the fund has accumulated to 10,000 marks before making a grant of the interest, which alone is to be expended, the capital remaining intact. Grants will be made with a view to giving young geographers the opportunity of travel and research, and the recipients must be Germans or Japanese, while preference will be given to students in the University of Bonn and in the Commercial College at Cologne. The fund will be admin-

istered by a small committee, on which Professor Rein will serve during his lifetime.

Nature states that the council of the Royal Sanitary Institute offers the Henry Saxon Snell prize for competition this year. The prize was founded to encourage improvements in the construction or adaptation of sanitary appliances, and is to be awarded by the council at intervals of three years, the funds being provided by the legacy left by the late Henry Saxon Snell. The prize will consist of fifty guineas and the silver medal of the institute, and is offered for an essay on "Suggestions for Improvements in the Ventilating, Lighting, Heating and Water Supply Appliances and Fittings for an Operating Room and its Accessory Rooms for a General Hospital of 400 Beds."

THE conference of representatives of forty-two states which was convened last November under the auspices of the International Office of Public Hygiene, and which has been sitting in Paris under the presidency of M. Camille Barrère, the French ambassador in Rome, has now signed a convention making regulations for the prevention of pestilential diseases, especially plague, cholera and yellow fever. This agreement supplements the earlier Paris convention of 1903 in accordance with the latest scientific requirements.

THE annual meeting of the Illinois Society of Engineers and Surveyors for 1912 was held at the University of Illinois on January 17, 18 and 19. The more important engineering topics discussed were stream pollution, sewage disposal, accuracy in surveying, road and pavement problems and the bridge work of the Illinois highway commission. Two illustrated lectures were given, one by Professor I. O. Baker on the Panama Canal, and one by Mr. H. L. Cooper, chief engineer, on the Keokuk Water Power Plant. An afternoon was spent in inspecting the buildings and discussing the work of the College of Engineering.

THE Physical Science Club of Oberlin College is an organization composed of instructors and students in the departments of chemistry and physics, with affiliated members

drawn from the departments of botany and zoology and mathematics. The most recent open meeting of the club was devoted to a lecture by Professor A. W. Menzies, of the University of Chicago, who spoke on "The Uses of Quartz in Physical and Chemical Apparatus." Recent regular meetings of the club have been devoted to talks and illustrated lectures by E. J. Moore, associate professor of physics, who has been for two years working in the laboratories of the University of Chicago under Professor Millikan. Dr. S. R. Williams, head of the department of physics, has read a series of papers on "A Model of the Elementary Magnet," while Professor G. D. Hubbard, head of the department of geology, has brought to the meetings the results of his work under the State Geological Survey, on the investigation of preglacial conditions and present topography in the Ohio Valley.

In connection with the Centenary Celebration of the Academy of Natural Sciences of Philadelphia, the following invitation has been mailed to correspondents.

The Academy of Natural Sciences of Philadelphia, founded in the year eighteen hundred and twelve for the cultivation of the natural sciences, in March nineteen hundred and twelve will have completed one hundred years of active devotion to this purpose.

For the adequate celebration of its centenary anniversary the Academy will call in convention at its Hall the learned men and institutions of the world—its collaborators.

The Academy has the honor to invite to be present at this event which will take place at Philadelphia on Tuesday, Wednesday and Thursday, the nineteenth, twentieth and twenty-first of March nineteen hundred and twelve.

UNIVERSITY AND EDUCATIONAL NEWS

THE council of Bedford College has announced that the £100,000 required to erect the new buildings at Regent's Park and to inaugurate an endowment fund has now been obtained. Of this amount the London County Council has contributed £30,000.

PROFESSOR HENRY WILLIAMSON HAYNES has bequeathed to the Peabody Museum of Har-

vard University \$1,000 for the library and all his prehistoric and archeological objects, and his books and pamphlets relating to such subjects. To the Boston Society of Natural History is given his fossils, minerals and other objects of natural history. To Harvard College is given, for its classical department, Mr. Haynes's Etruscan, Greek and Roman vases and his ancient coins and medals. The Boston Museum of Fine Arts is to receive his Egyptian antiquities, except those relating to the age of stone in Egypt, which go to the Peabody Museum.

THE dedication of the New York State Education Building will take place on October 15-17. It is expected that educational officers of other states will attend the exercises and that the leading institutions—including libraries and museums as well as universities, colleges and schools—of this and other countries will be represented by delegates.

THE entrance requirement to the College of Medicine of the University of Cincinnati will be advanced to include two premedical years in science, after June 1, 1913.

ANNOUNCEMENT is made that at the University of Pittsburgh instruction in geology, paleontology and physiography will hereafter be given under the direction of the college instead of the School of Mines faculty, courses being offered in the department of geology by the following-named professors and instructors: Drs. C. R. Eastman (chairman), A. E. Ortmann, O. E. Jennings and Messrs. H. N. Eaton and Earl Douglass.

PROFESSOR H. R. SMITH, in charge of the animal husbandry work in the University of Nebraska, and Professor F. H. Stoneburn, professor of poultry husbandry in the Connecticut Agricultural College, have been called to the University of Minnesota.

MR. C. W. HOWARD, of Cornell, known in connection with grasshopper work in South Africa and at present with the Rockefeller Institute, has been appointed to an instructorship in the division of entomology, University of Minnesota. Mr. O. G. Babcock, of College

Park, Maryland, has been appointed as assistant to the entomological division in charge of the insectary. These two appointees take the places of Mr. C. S. Spooner and Mr. H. B. Seammell, respectively. The former goes to Georgia, accepting an offer from the state entomologist there, and the latter has been elected county inspector of nurseries and orchards in Colorado.

DR. B. W. VAN RIPER, of Nebraska Wesleyan University, has been elected assistant professor of philosophy in Boston University.

AT Smith College Elizabeth Kemper Adams has been promoted from associate professor of philosophy and education to professor of education; Aida Agnes Heine, from instructor to associate professor of geology, and Helen Ashurst Choate, from assistant to instructor in botany.

DISCUSSION AND CORRESPONDENCE

THE PRIBILOF FUR SEAL HERD

IN SCIENCE of February 2, 1912, Mr. McLean, of the Campfire Club's Committee on Game Protection, says, among other things about the diminishing fur seal herd, that "the best remedy is to let it absolutely alone."

Nature's methods are wasteful,

So careful of the type she seems,
So careless of the single life.

Civilized countries practise artificial fertilization of fish eggs, and rearing of the fry in hatcheries, because a greater proportion of eggs can be fertilized, and vastly more young brought to maturity, than by nature's methods. The domestication and control of useful animals is universally practised for similar reasons.

That the fur seal tribe would slowly increase if "let absolutely alone" may be true. So would most other beings we are at such pains to cultivate. Pelagic sealing is responsible for the present abnormal condition of the seal herd. The state department's bill for the ratification of the treaty for the suppression of such sealing, *gives the female seals the first chance they have had for twenty-five years.* The fact that we have forty thousand breeding females on the

islands to-day is attributable to our consistently practised rule of keeping down the hordes of dangerous males on land, while pelagic scalers were destroying the female stock.

The Bureau of Fisheries should not be hampered in carrying out its arrangements for a more rapid increase of the herd than nature unaided can effect.

Great Britain, Japan and Russia are to profit by the cessation of pelagic sealing, and ill-advised amendments would render the treaty ineffective, which would be deplorable. A naturalist and a member of the fur-seal investigation commission of 1896-97 for Great Britain, now writes me that

There is no doubt that fighting bulls have caused incalculable injury to the seal rookeries, and judicious killing of the males should be carried on from the date that there is known to be more than a sufficient supply for breeding purposes. There is no doubt that with proper management an increasing number of the surplus males may be killed every year with great advantage to the rookeries.

This is talk from a man who worked with us for several seasons on the Pribilofs.

Are the dozen or more naturalists who have devoted many seasons to studying the fur seal on the Pribilofs, and have long worked for the cessation of pelagic sealing, to be deprived in the end, of the opportunity to put into practise what they believe to be a rational system of fur-seal farming. If congress should be persuaded to let sentimentalists dictate the policy to be pursued on the national seal farm, it would mean a *very slow rehabilitation of the seal herd*. We can not afford to ignore what has been learned about the fur seal by the patient investigations of the past twenty years, and take a step backward.

Last November I had some correspondence with a member of the house of representatives who was taking the agitation of the Campfire Club against the killing of surplus male seals very seriously. I quote the following from a letter I wrote to him at that time:

In order to prevent annual loss of new-born young we must prevent the flooding of the breed-

ing grounds by big males. The logical way to do this is to market a large proportion of the three-year-olds, as we always have done, and thus prevent them from growing up into valueless but dangerous and destructive supernumeraries.

I take exception to the line in your letter "unless the herd is further depleted by the Bureau of Fisheries." The herd is not to be "depleted," as the females are already saved for fifteen years by the cessation of pelagic sealing, but the polygamous male part of the herd must be depleted (to quote your word again) if you propose to mature all your annual crop of infant seals. Nature will do the *depleting* if you don't, and *half the loss will be female pups*.

Surplus bull seals are of no more use than surplus rams or roosters. By saving them you will lose, in fifteen years, not less than \$15,000,000 of revenue.

The present revenue from the islands is over \$400,000 a year, which in fifteen years would amount to \$6,000,000, *without any increase of females*. But the females will increase, and the loss of revenue will exceed \$15,000,000 in fifteen years closed season, and you will lose an important percentage of pups besides.

This is not the first time I have endeavored to prevent well-meaning congressmen from being deceived by the misrepresentations which have been poured upon them for many years. The mischief-maker referred to has bobbed up every other year for the past eighteen years and has been discredited every time. I hope you will look up his record as just published in H. R. Doc. 93, 62d Congress, 1st Session, pp. 1153-62.

The member of the house to whom I sent this letter has at last presented an amendment to the State Department bill in which he proposes to limit the killing of male seals to 5,000 a year for five years, 7,500 a year for the following five years and 10,000 annually for five years after that. At the end of fifteen years new regulations to be adopted.

Now that is better. The gentleman has evidently been thinking it over. We shouldn't probably kill much closer if allowed to have our own way. Perhaps by the time the treaty bill reaches the senate, congress will decide that the Bureau of Fisheries is able to handle the seal fishery safely for the seal herd and for the government.

As to the criticism of my general statement about the *Uncinaria* parasite, I can only reply that our diminished rookeries are *not at present overspreading into the parasite-infected sand areas*. In fact, Mr. Heath states, as quoted by Mr. McLean, "these areas have been abandoned." They must of course be fenced to protect the younger seals from infection as soon as the breeding grounds begin to expand. As to shooting some of the big males when they get too numerous, it would puzzle the experts, as well as Mr. McLean, to say which were the fittest to survive. They all look alike. Old Ocean attends to the matter of selection in the case of the fur seal, weaklings do not survive the seven-month's migration swim among the killer whales of the Pacific. If Mr. McLean will bring his committee to my office where there is a fairly complete set of rookery photographs and charts, he will get a clearer understanding of the Pribilof breeding grounds than he has at present. The fact is that the innocent Camp Fire Club is being used by the unscrupulous lobby which has always been kept at work by the pelagic sealers. One excuse suits it as well as another, this time it is the killing of surplus males. It is a pity that year after year it should succeed in getting the support of men of good standing who happen to be ignorant of the real facts involved.

C. H. TOWNSEND,
Member Advisory Board
Fur Seal Service

TO THE EDITOR OF SCIENCE: IN SCIENCE for February 2, Mr. Marshall McLean, member of the Camp Fire Club, enters the list of those who would by indirection ruin the fur seal herd. He would have "natural conditions" rule upon the fur seal islands and "all killing of selected males for commercial purposes . . . cease until the tide of increase in the fur seal herd has once more set toward the flood." He lays down as reason for this the principle "that when any species of wild animal has become so depleted as to be in danger of extinction, the best remedy is to let it absolutely alone."

Singularly enough he quotes President David Starr Jordan in support of his position. The quotation, however, is from an essay on the effects of war, the selection of the most fit for military service and their destruction in war tending to reverse the process of natural selection under which the fittest should survive. The assumption of Mr. McLean is that the killing of fur seals, as practised on the islands, is a selection out of the best, leaving an inferior quality of males to breed. President Jordan would not admit this and is in fact utterly opposed to any scheme for the suspension of land killing as at present conducted.

To do President Jordan justice in the fur seal matter quotation should be made from his reports on this subject which followed the investigations made in 1896-97 under his direction. On page 147 of Vol. 1 of the final report of the Commission, speaking of a *modus vivendi* similar to the one which Mr. McLean would institute, which prevailed in 1891-93, he says:

The suspension of killing on land only released young males to grow up which are now, as idle and superfluous bulls, a menace to the rookeries.

Again, on page 120 of the same volume,

Moreover, the removal of this superfluous male life is not only possible, but it is really beneficial to the herd. The only deaths among the adult bulls and cows, discovered upon the rookeries of the islands, resulted from the struggling of the bulls among themselves or to attain possession of the cows.

In the investigation of 1896-97 a number of eminent scientists from the Smithsonian Institution were associated with President Jordan and a commission of British scientists made a concurrent investigation. These men came together as a joint Conference of Fur Seal Experts in Washington at the close of the investigation and agreed upon a statement of facts regarding the fur seals. The full text of the finding of fact of this Conference will be found on pages 240-244 of Vol. 1 of the final report of the American Commission.

Mr. McLean should read this document. In Article 9 occurs this statement:

The methods of driving and killing practised on the islands, as they have come under our observation during the past two years, call for no criticism or objection. An adequate supply of bulls is present on the rookeries; the number of older bachelors rejected in the drives during the period in question is such as to safeguard in the immediate future a similarly adequate supply; the breeding bulls, females and pups on the breeding rookeries are not disturbed; there is no evidence or sign of impairment, by driving, of the vitality of males; the operations of driving and killing are conducted skillfully and without inhumanity.

In Article 13 it is further stated:

The polygamous habit of the animal, coupled with an equal birthrate of the two sexes, permits a large number of males to be removed with impunity from the herd, while, as with other animals, any similar abstraction of females checks or lessens the herd's increase, or when carried further, brings about an actual diminution of the herd.

Passing to the side of pelagic sealing the Conference of Experts has this to say:

Article 11. Pelagic sealing involves the killing of males and females alike, without discrimination and in proportion as the two sexes coexist in the sea. . . . In 1895 Mr. A. B. Alexander, on behalf of the government of the United States, found 62.3 per cent. of females in the catch of the *Dora Seward* in Bering Sea, and in 1896 Mr. Andrew Halkett, on behalf of the Canadian government, found 84.2 per cent. in the catch of the same schooner in the same sea.

These quotations from the findings of fact of the experts are more guarded than would have been the same statements made by the American Commission alone, but they state with sufficient clearness the effect of land killing and pelagic killing in their relation to the herd. They offer little support to the contention of Mr. McLean.

At the same time President Jordan would recognize that the law of the survival of the fittest applies to the fur seals. The seat of the operation of this law is, however, at sea and not on the land. The fur seals spend the winter in the open ocean. They get all their

food at sea. The difficulty of obtaining food and the buffeting of the severe northern winter constitute the sifting process by which the weak and ineffective fur seal, male or female, is ruthlessly weeded out, leaving only those that are absolutely fit to return to the islands in the spring. The killing gang does not select out the best. They are all alike good. It selects its animals by ages, an animal of three years giving a larger and hence more valuable skin.

But the question at issue is not a theoretical one. For the past fifteen years pelagic sealing has been the recognized sole cause of the decline of the fur seal herd. On July 7 last the United States secured the agreement of Great Britain, Russia and Japan to a treaty for the abolition of this form of sealing. This treaty obligates the United States to pay to Canada and Japan fifteen per cent. each of its land catch, these nations buying off their pelagic sealers. It is only necessary to put this treaty in effect by act of Congress, the Sulzer bill now before the House having this end in view. But opposition to the bill arises. It takes the form of an amendment providing for a "zaposka" or close season of fifteen years, coincident with the term of the treaty, in which there shall be no land sealing. That is, the government is to have no land catch to share with the cooperating nations. They will become dissatisfied, withdraw from the treaty, and pelagic sealing will be resumed. Such is the inevitable trend of this misguided effort to which the Camp Fire Club is wittingly or unwittingly lending itself.

The principle laid down by Mr. McLean may apply to pairing animals like the deer, bear, duck or quail. But the fur seal is a polygamous animal and has nothing in common with these wild creatures. Its true analogies are with the domestic animals—cattle, horses, sheep, poultry—which man handles for his comfort or profit and from which he regularly removes the superfluous males without damage to the breeding stock. Would Mr. McLean have us believe that the way to recuperate a herd of cattle that had fallen into decline

through the illicit killing of its cows and calves was to leave it absolutely alone? A cattle man would stop the killing of the females and young, would look out for a reserve of bulls, and market his steers as usual. Especially would he do this if it were necessary for him to pay for the cooperation of his neighbors in suppressing the illicit killing.

Mr. McLean would have us take a different course. He would have the government begin by depriving itself of an immediate income of about \$400,000. The herd has probably yielded this amount in the lowest year of its existence. This income has possibilities of indefinite increase with the recovering herd. But there would be no increase. With no quota to share with the cooperating nations the treaty would lapse. Pelagic sealing would be resumed. The herd would continue on its way to extinction. Is this what Mr. McLean and the Camp Fire Club want?

ANOTHER VIEW OF THE PRINCIPLES OF WATER-
POWER DEVELOPMENT

IN SCIENCE of December 15 the foremost place is given to Dr. W J McGee's statement of the above-mentioned principles. As the subject is one of general scientific interest, I beg leave to present it from a different point of view.

A couple of centuries of legislation, following decade by decade the settlement of the country and the appropriation and use of its waters for power, irrigation, etc., have left little scope for the application of Dr. McGee's principles, at least on the part of the federal government. He writes as if he were laying out plans for a continent not yet occupied by human beings. It may as well be recognized that in the older part of the United States the more desirable water powers have all passed completely into private ownership. The practical application of his principles, if there be any, must then be in the newer, and chiefly the western, part of the United States. But

even here irrigation waters are already appropriated very generally except in those not rare cases where a large capital is required for the first installation. Water-power can not be dissociated from the subject of irrigation in the west, because the same water often serves both purposes, and may even be taken away from one to serve the other. It is surprising to see all through the west that every spot where irrigation can be cheaply applied to good soil has been farmed with the aid of water for many years. Many cases have come under my observation, from forty to a hundred miles from a railroad, where irrigation has been practised for thirty or forty years, generally up to the limit of the water supply or of the good land. It is very late in the day to talk about the general principles which should govern the framing of laws on irrigation, but it is astounding to read (McGee's principles 34 and 36) that legislation at present should be tentative and experimental. Every western state has voluminous laws on the subject, and ten times more voluminous legal decisions on those laws. The general principle has had full acceptance for a long time that the states have complete authority over the use of waters within their respective borders except for the purpose of navigation and in a few unusual cases. While there is a "borderland" here that is not worked out, there is no reason to suppose that the general control of its own irrigation waters by the state will be materially impaired.

This control necessarily extends to the public lands within the state. In nearly every case where the settler puts in a small irrigation system for his own use, his head-gate and the most of his ditch are on government land, since he has to go some distance above his own land to get the fall requisite. A later homesteader above him can not disturb his ditches, even though occupying a tract across which they run. This policy runs back almost beyond history, and is as well settled as anything can be.

Turning now to the subject of water-power, we find that all the western states have pro-

vided definite methods by which it may be appropriated, as in the case of irrigation waters. Even on public lands the authority of the state has until lately not been questioned. But with the rise of the conservation movement there has come about a demand that the federal government assert a right to the disposal of water-powers on public land, and especially in national forests. This demand has its origin in the belief that the western states are allowing the water-powers to be monopolized, and are in danger of losing all right of subsequent regulation, so that the public served by the power will be compelled to pay "all that the traffic will bear."

In the absence of any explicit law or precedent for federal interference with water for power or irrigation, the proponents of the policy have grasped at general constitutional powers, such as "to promote the general welfare," or the right to control navigation in rivers and internal waters. President Taft a year ago favored the assertion of a claim to the banks of the stream by the federal government, so that the *site* would become paramount to the *water* in a power installation, conceding that the state had exclusive jurisdiction over the latter; the interposition of a technical claim to the stream banks would, in his opinion, operate to prevent the establishment of any power plants without federal approval, even though the government had no claim on the water. This admittedly technical and strained position is just about paralleled by his proposal that, since we have solemnly pledged our word to other nations that we will make the tolls in the Panama Canal equal to all, we will make some sort of a subsequent gift to our own vessels to equal the fees paid by them. The good intention we all concede, but lament the facile readiness to "beat the devil about the stump."

This is not the place for an adequate discussion of the safeguards which the western states have placed around the disposal of water power, nor for a description of the propaganda by which, largely through misrepresentation, many people have been made to believe that

only in federal control could there be any assurance of permanent management in the interest of the people. Enough to mention that fundamental safeguards are two—forfeiture for non-use, and the reservation of regulatory powers by the state. Both of these are embodied in the constitution of Idaho.

But the most notable principle enunciated by Dr. McGee is his No. 30. It is as follows:

30. The essential principle of natural equity on which specific legislation may rest has already found expression, both by statesmen and by powerful associations of citizens including both jurists and publicists, in the incontrovertible proposition—now become axiomatic—that *all the water belongs to all the people*.

So far is this principle from being true, either legally, equitably, or even as an ideal relation, that the reasonableness of the opposite view will appear immediately on stating it. If Dr. McGee is correct, then the general government should collect as a tax on every water power the full value of the power above a reasonable interest on the cost of installation; from every user of irrigation water it should collect the difference in value between what will grow with water and without it, minus the cost of applying the water; from every municipality a tax on its use of water; even from the owner of a well a proportionate assessment. Otherwise the people as a whole can not derive the benefit which their ownership of all the water ought to entitle them to. A closer analysis would necessitate even a farther extension of water taxation, for it is obviously unjust to tax the western user of irrigating water while the eastern farmer is allowed the free use of rain-water. Such are the absurdities into which we are led if we admit the principle that all the water belongs to all the people.

Is it possible to express in a simple way the correct principle as to ownership of water? Not in all relations, because of their variety. But some are unquestioned: a man owns the water in his well, we all believe; he has a right to the benefit of what falls from the sky on his land; communities rightly own the water that flows through their mains to their citi-

zens. So far all agree that the present legal relations could not be improved; they are substantially ideal.

How about water for irrigation? Prior use is the determining element in ownership, according to the laws in all the western states, and continuity of use is the element which perpetuates the title. This is the simplest possible plan, and taken all in all is the most feasible one, and works as little hardship as any.

Now about water for power. This is the "nub" of the whole matter for the conservationist, and is probably all that Dr. McGee had in mind in enunciating his principle, which seems so fundamental to him as to be "axiomatic," "incontrovertible," and even (principle 38) "a part of the body of ethical conviction underlying American character and constituting its strength." In the face of these overwhelming assertions, I will undertake to maintain that the people as a whole have no interest whatever in any specific water power. A portion of the people are in each case interested, those who are in a position to make a reasonable use of the benefits of the power, but the rest have no right whatever to claim a share by taxing those more favorably situated with reference to this particular power site. To illustrate: the Snake River in southern Idaho has several large falls, principal among them being Shoshone Falls, with Twin Falls second. These have been partially developed, and a large amount of power, light and heat can be obtained from the present installation. Now what part of the people of the United States are equitably interested in what is being done here? Simply those who live within the range of power transmission, and are not more accessible to another source of power. These people, in a very real sense, have an interest in that water power, and have a right to be protected from extortion by the laws of the state, and as a matter of fact they have a recourse in the constitution of Idaho. But the people of Cape Cod, or of Washington, D. C., have no equity in Shoshone Falls, and no right to expect dividends from its successful development. This is not

only ideally sound in principle, but it is recognized in law and embedded in the whole organization of state and nation.

Differences of opinion in regard to policies of conservation have had their origin very largely in loose and vague thinking such as is illustrated by Dr. McGee's principles. Not realizing that the west has been facing these problems for decades, and has pretty nearly settled them, a class of theorists in the east has taken up the same subjects *de novo*, treating them as if they had never before been touched by the hand of man and the way were free for any sort of plan to be carried out.¹ I do not accuse all conservationists of being so visionary, but Dr. McGee represents something of an element. It wearies the patience of the people of the west to be obliged to deal with such persons, who have a missionary zeal to teach us things we have always known, and know much better than the would-be teachers, and who would view us as either a set of thieves and robbers or helpless children whom they would protect. Our best reliance is ourselves; we are amply clothed with authority to do all that is necessary; our experience and training have familiarized us with the work ahead; and our purpose is to protect the interests of the public, our own public, ourselves, in all necessary and reasonable ways.

J. M. ALDRICH

FIRST USE OF WORD "GENOTYPE"

I HAVE recently asked Dr. J. A. Allen, the leading authority in this country on nomen-

¹A beautiful illustration, which I will not charge to Dr. McGee, is in the withdrawal of power sites from entry under the public land laws. It was a great relief to many eastern conservationists when sweeping withdrawals of this class were made a few years ago; but in fact under the laws of Idaho the acquisition of a water power is a process entirely apart from the filing of any sort of entry on land, and the withdrawal did not change the legal status of the power sites by one iota. The mode of acquisition of water power under the laws of the state is precisely the same as before, and I doubt not that the same is true in other western states.

clature, to express an opinion upon the first use of the word "genotype." He writes, January 30, as follows:

I can not give the date of the first introduction of this word to replace the phrase "generic type," but I find it was used as early as 1903, as apparently a word not new. By 1905 it was in common use in discussions of generic types and prior to 1910 it became officially adopted by the International Zoological Commission. I think the first use of the word was by some writer in *Nature* or in the *Annals and Magazine of Natural History*.

The word is derived from the Greek word *γένος* = kind, *genus* and *τύπος* = type. The use of "o" as a connecting vowel seems to be consistent with general usage in such cases. The derivation of "genetic" is given in the Century Dictionary as from *γένεσις* = generation, genesis.

I will try to trace it to its origin, and, if successful, report again on the subject.

This note by Dr. Allen raises the question as to the use of "o" as the connecting vowel in the term "genotype" proposed by Johannsen. Why not use "e" as the connecting vowel, as in genetic, genesis, etc.? This would obviate the confusion which is bound to arise and persist if the preoccupied term "genotype" is adhered to. It is such a valuable conception of Professor Johannsen's that it seems worth while to have a permanent and undisputed designation for it.

SCIENTIFIC BOOKS

Grundzüge der Paläobiologie der Wirbelthiere.

By O. ABEL, Professor of Paleontology in the University of Vienna. Stuttgart, E. Schweizerbart. 1912. Pp. xii + 708, frontispiece and 470 text illustrations.

This extremely interesting and highly important treatise is in effect a text-book of adaptation among the vertebrates past and present. The subject is, as Doctor Abel observes, the most recent development of paleontologic science. Speculations, indeed, on the habits and environment of extinct animals are as old as the first finding of their fossil re-

main. But the systematic study of the subject, analysis of the adaptive characters of living animals and interpretation of the adaptation of extinct animals, is a development of the last few years. It requires as its groundwork thorough morphologic study of complete skeletons, which until recent years have been very rarely available among fossils.

The subject is a fascinating one—somewhat speculative in the present stage of its development, for the criteria of adaptation are not yet perfectly worked out or thoroughly tested. But it lends to these dry bones a living interest that a systematic treatment lacks, and a faunal or even a phylogenetic treatment imperfectly supplies. Doctor Abel has given particular attention to this phase of paleontology and his work is authoritative, especially in the field of marine adaptations. The subject is clearly presented and well illustrated.

The volume opens with a sketch of the development of paleontologic method. Then follows a discussion of the causes, conditions and processes of fossilization. The principal portion is devoted to the various adaptations of vertebrates, especially of fossil vertebrates as interpreted by modern adaptations, and a full discussion of the criteria of adaptation in external form and in construction of feet, teeth and other parts. A final chapter discusses the relations of paleobiology and phylogeny.

The analyses of the various adaptive types with their parallel and divergent characters are admirably clear and serve to bring together the latest results of studies in *ethology*, as the study of adaptation is called by Dollo. The illustrations are numerous, well chosen and instructive.

The entire volume is surprisingly free from errors of fact—such criticisms as may be made are in matters of interpretation and theory. Doctor Abel is perhaps a little prone at times to accept the theoretical conclusions of others without sufficient critical sifting of the evidence, and here and there one finds difficulties in reconciling conclusions which in truth are based upon mutually exclusive data.

The volume is crowded with novel sugges-

tions and interpretations of adaptation of various extinct races. Most of them will be welcomed and accepted; some may need further consideration; a few seem open to serious criticism. The discussion of the carnassial teeth of carnivora ignores their most essential feature, the shearing adaptation. The hypothesis that the inner digit of the fore foot in amphibia is primarily absent, and its presence in reptilia and mammalia is a "neuerwerbung," will not commend itself to many; nor will the interpretation of the Stegocephalia and Cotylosauria as fossorial adaptations be readily reconciled with the strikingly paddle-like construction of the feet in these animals, especially the former. But these and a few other points are occasional lapses from the normally high standard of thorough and up-to-date information and good judgment. The book will rank as one of the most important and readable contributions to paleontologic literature, and be indispensable to every one who wishes to understand and teach the real meaning of extinct animals and their relations to the world in which they lived.

W. D. MATTHEW

Inheritance in Maize. By E. M. EAST and H. K. HAYES.

This is an interesting and important contribution from the Bussey Institution of Harvard University, which has appeared as Bulletin 167 of the Connecticut Agricultural Experiment Station. It presents a very thorough study from the Mendelian standpoint of a number of characters of the Indian corn plant and their method of transmission. The interest in this study, however, is by no means confined to its connection with the improvement of this, our greatest agricultural crop, for many of the principles involved have a significant bearing upon several of the more general problems of heredity.

The bulletin, embracing as it does so many different considerations, scarcely admits of a summary that would be short and at the same time intelligible. It is the present purpose, therefore, merely to indicate the general plan and scope of the work by mentioning briefly a

few of the many interesting points touched upon.

After a short introduction in which the authors point out the advantages and disadvantages offered by the maize plant as material for study of genetics, the subject is conveniently divided into five parts.

In Part I. is presented the *material and the problem*, and the corn plant, *Zea mays*, is considered in its systematic relationships. Different classifications are considered, but the well-known one of Sturtevant, slightly modified, is finally adopted as being the most practical and convenient. In this connection there is some speculation in regard to the origin of maize based upon the facts brought out in the investigation concerning the transmission of its characters. After reviewing briefly some of the theories proposed by other authors the suggestion is here offered that maize is derived from teosinte or some similar plant. The maize ear represents an evolutionary product derived by progressive meristic variation of the central spike of the lateral tassels of the teosinte. Other changes are to be accounted for in the accession or dropping of characters, the transmission being in accordance with Mendel's principles.

Mention is then made of the work of previous investigators of inheritance in maize. It is interesting to note how very close some of these workers were, in the days of the eighties and nineties, to the rediscovery of Mendel's law, yet failed to recognize its operation in their results. It is also interesting to note that *Zea mays* is the plant that furnished the data which finally did lead to the rediscovery of the law on the part of both de Vries and Correns.

Next follows a catalogue description in detail of each of the twenty-nine ears of corn that formed the parentage of the various hybrid combinations used in this investigation. Experimental methods and precautions are described. Very much of the value of this report depends upon the painstaking care with which the investigation was carried out, as for example, the previous inbreeding of all the stock used, in order to establish purity. An-

other tremendous advantage is gained by going to the trouble of making separate pedigree cultures of the various lines, thus admitting an analysis of results, such as was sometimes impossible in the case of the work of previous investigators in this field.

Part II. deals with *endosperm characters*, and under this subject is taken up first the transmission of starchiness of endosperm. Although the behavior of this character as to dominance and segregation is already known, the matter is made the subject of an unusually thorough and critical study here because of the sharpness and completeness with which starchiness segregates and with the idea of applying this study to some fundamental principles in their connection with Mendelism, such as prepotency and gametic purity. In all the large number of cases examined the behavior in this respect is found to be so regular as to force the conclusion that "the mechanism by which the members of an allelomorphous pair are distributed among the gametes is accurate," and none of the extra explanations offered by some other investigators to account for discrepancies are needed here.

In connection with the transmission of yellow and non-yellow endosperm, an important principle is brought out; namely, that in certain strains of corn yellowness is not a simple unit, but rather is the result of two distinct and independent yellow units or factors operating to give precisely a di-hybrid effect. This is an important observation, in that the same principle may be carried to various other characters supposed to be simple, but which in reality may prove, upon more critical analysis, to be compound, depending upon the operation of a series of units or factors.

The transmission of endosperm colors has been left rather vague by the experiments of previous investigators in this field. Some of the discrepancies in the results of Correns and of Lock with respect to the behavior of purple aleurone colors are now explained by the present investigation; thanks to the separate pedigree culture making possible a more thorough analysis of data. It is found that the

behavior in this regard is not always constant, but varies in different strains or families, apparently depending upon the constitution of the uniting gametes. The conception of certain developer and inhibitor factors serves to explain quite satisfactorily most of these cases, and it is believed that when all of the facts are known, most, if not all, of these discrepancies and contradictions will be similarly explained, and thus will be wiped out some more of the seeming exceptions to the law of Mendel.

Part III. is a discussion of *Xenia* and the observations here are in the main in accord with those of previous investigators. On account of the various effects of dominance in different cases some confusion has arisen concerning this phenomenon. An explanation of these cases is given in connection with which the following law regarding *Xenia* is formulated:

"When two races differ in a single visible endosperm character in which dominance is complete, *Xenia* occurs only when the dominant parent is the male; when they differ in a single visible endosperm character in which dominance is incomplete or in two characters both of which are necessary for the development of the visible difference, *Xenia* occurs when either is the male."

In Part IV. is considered the inheritance of a number of *plant characters*. In the case of the podded kernel the presence of pods is found to be a perfect dominant. In the investigation of pericarp colors a number of different kinds of reds are distinguished. Red in cob color was found to behave as a simple character in the cases examined, but red color in silks appears to be more complex in its inheritance.

A section is devoted to the matter of *physical transformation of starchiness*, and a study of the crosses between soft starchy and corneous starchy sort brings out the following three facts: "The characters that give the flint or the dent appearance to maize are transmitted as plant characters to the entire ear and not as endosperm characters to the individual seed. They conform to the essen-

tial feature of Mendelism by showing segregation; and they are due to the action of more than one transmissible character."

A discussion of *size characters* is next taken up, including observations on numbers of rows of kernels on ear, height of plant, length of ear and size of seed. Studies of these characters are naturally beset with complications, the results being often obscured by the influence of environmental effects. However, the experiments disclosed segregation with respect to these characters, and the conclusion is therefore drawn that size characters do mendelize. Perhaps the most important point in this connection is the suggestion that in such cases which have heretofore ordinarily been considered as continuous variations, we may actually have to do with a series of Mendelian factors in operation, naturally quite difficultly discernible on account of the complex polyhybrid ratios involved, the absence of dominance, and the obscuring effect of environmental influences.

Part V. contains an account of a number of interesting *abnormalities* which arose among these various cultures. The appearance of several dwarf plants is described, but their significance is rather obscure, since no ratios were obtained. Bifurcated ears transmitted this abnormality as a dominant. In the case of striped foliage arising as though by mutation in some of these strains, the striped plants are considered to be heterozygous.

Aside from the interesting content of the bulletin, the authors are to be congratulated on its general appearance and make up. It is well illustrated by 25 plates of excellent photographic reproductions. The data are well chosen and presented in very convenient arrangement.

L. H. SMITH

NOTES ON METEOROLOGY AND CLIMATOLOGY

THE MOST NORTHERLY SCIENTIFIC INSTITUTION

THE weather observatory recently established by the Norwegian Meteorological Institute at Spitzbergen, 1,100 miles north of Christiania, is the most northerly permanent scientific institution of any kind in the world.

Meteorological data are communicated to the central office by means of wireless telegraphy via Green Harbor. The progress made at the observatory may be watched with interest, as it is hoped that the data there obtained will aid in European weather forecasting. The Norwegian project is separate and distinct from the German expedition, headed by Drs. Wagner and Rempp, which is now carrying on research in aerology and geophysics in Spitzbergen.

THE ANNUAL REPORT OF LINDENBERG OBSERVATORY

THE report of the Royal Prussian Aeronautical Observatory at Lindenberg for the year 1910 has recently appeared. As has been the case during several years, preceding, upper-air investigations were conducted daily, without a single exception, throughout the year. The meteorograph was elevated by means of kites 459 times, and by means of captive balloons 211 times, the average height with the former method being 9,866 feet, and with the latter 9,898 feet, both of which are higher than the corresponding averages for any earlier year. Of 29 registering balloons sent up 27 were recovered, and the average height attained was 49,028 feet (9.3 miles). On August 20 the greatest height yet reached at Lindenberg was recorded, the barograph indicating a height of 82,138 feet (15.6 miles). 177 pilot balloons carrying no recording instruments were also sent up during the year, data of wind velocity and direction aloft being obtained from these ascensions. In addition to the aerological data, which are printed in detail, the report contains five papers prepared by various members of the observatory staff.

WATER VAPOR IN THE ATMOSPHERE

IN observations with a telescope, bolometer or pyrheliometer the approximate amount of water vapor in the atmosphere is an important factor. The determination of this amount by spectroscopic methods is not very satisfactory. In order to simplify the evaluation of this factor Professor W. J. Humphreys has examined the data obtained in 74 balloon flights made on cloudless days. Conditions on

cloudless days alone were considered, since in practical work a knowledge of the moisture content is needed only upon such days. The data used pertain to Europe alone, but presumably are fairly representative of conditions everywhere, since they cover the observations of several years and were obtained at many different places. Though the amount and the distribution of the water vapor in the atmosphere varies greatly from day to day and from place to place, it is interesting to learn that there is a tendency toward a maximum of humidity just above one of the levels of maximum cloudiness, the cumulus level. While there were no clouds at this or any other level at the times of observation, the water vapor was relatively abundant there, and, though not dense enough to produce a cloud, was made manifest by the readings of the hygrometer. Among the conclusions stated by Professor Humphreys (*Bulletin of the Mount Weather Observatory*, Vol. 4, Part 3) are the following:

The amount of water vapor per unit volume decreases with elevation in an approximate geometric ratio, and the thickness of the water layer that would result from a condensation of all the water vapor in the atmosphere above any given level, whatever the season, so long as cloudless days are used, may be approximately expressed by the equation, $d=2w$, in which d is the depth of the water layer in millimeters and w the weight in grams of the water vapor per cubic meter at the given level or place of observation. An alternate, and probably equally good expression, is, $d=2e$, in which d , as before, is the depth of the water layer in millimeters, and e the partial pressure of the water vapor in millimeters of mercury.

Professor J. Hann had previously concluded, from observations made upon all kinds of days, regardless of cloud, that $d=2.3e$, or about 15 per cent. greater than the value now found for clear days.

NEW BOOKS

AMONG the books which have recently appeared are: (1) "Thermodynamik der Atmosphäre," by Dr. Alfred Wegener. Leipzig, J. A. Barth, 1911. 8°. 331 pp. (2) "Aeronautische Meteorologie," Teil II., by Dr.

Franz Linke. Frankfurt a. M., F. B. Aufarth, 1911. 8°. 126 pp. (3) "Climatic Control," by L. C. W. Bonacina. London, Adam and Charles Black, 1911. 8°. 167 pp. (4) "Studie über Licht und Luft des Hochgebirges," by Dr. C. Dorno. Braunschweig, F. Vieweg & Sohn, 1911. f°. 153 pp. (5) "Dynamic Meteorology and Hydrography," Part II., Kinematics, by V. Bjerknes and different collaborators. Washington, Carnegie Institution of Washington, 1911. 4°. 175 pp. (6) "The Clouds and Fogs of San Francisco," by Alexander McAdie. San Francisco, A. M. Robertson, 1912. 8°. 106 pp.

EXCESSIVE PRECIPITATION

DURING the month of July last, Luzon, the largest of the Philippine Islands, was visited by three typhoons accompanied by rains which are among the heaviest on record anywhere upon the earth. The precipitation accompanying the first typhoon was greatest at Baguio, the summer capital and official health resort of the islands. The rainfall there, as registered by an automatic gauge of standard design, was as follows: 14th, 34.64 inches; 15th, 28.88 inches; 16th, 16.73 inches; 17th, 7.89 inches—a total of 88.14 inches in four days. (The mean annual rainfall for New York City is 45 inches.) The second storm was severest at Bolinao, where 26.69 inches of rain fell during July 26 to 27, inclusive. With the third typhoon, that of July 30 to August 2, inclusive, 23.80 inches fell at Candon, while Baguio received an additional 20.14 inches. Naturally the floods following these unprecedented downpours did enormous damage. The \$2,000,000 military road stretching for 52 miles over the mountains between Dagupan and Baguio was seriously damaged. It had previously been forecasted that this road, regarded as one of the engineering feats of the islands, would remain "until the Pyramids crumbled." The rainfall at Baguio during the four consecutive days of the first storm has rarely been exceeded anywhere in recent times. The only records of greater amounts for a similar period are: (1) 101.84 inches at Cherrapunji, India, June 12 to 15,

inclusive, 1876, and (2) 96.50 inches at Silver Hill, Jamaica, in November, 1909. The Indian station, located upon the Himalayan slopes, near the Bay of Bengal, remains the wettest spot on the globe. It is reported that during one month, August, the rainfall measured 384 inches, and it is believed that the annual precipitation is over 600 inches.

A NEW WEATHER SIGNAL

SINCE December 1 a new marine signal consisting of a red pennant has been displayed by the United States Weather Bureau to signify the approach of high winds which would not justify the issue of the regular storm warning. It is known as the "small craft warning," as it is designed especially for the owners of fishing, towing, motor and yachting craft. The pennant is flown from the officially designated flagstuffs on the Atlantic, Pacific and Gulf coasts, as well as along the borders of the Great Lakes. Judging from recent press reports the innovation is proving of value to those for whom it was intended.

CONCERNING AVIATION FATALITIES

AMONG the suggestions which have been offered to explain various fatal accidents in aviation recently is that which one aviator describes as "ethereal asphyxia, a dreadful something which lurks in the upper air and creeps irresistibly upon the senses of the aviator, lulling him into a dreamy unconsciousness." He declared that it was not due to rarefied atmosphere, as there was no stifling, choking or pain in the ear-drums, such as often results from decreased pressure. The falsity of the explanation is apparent to any one who considers the matter, for aeronauts have, for more than a century, ascended to far greater heights than the aeroplane has yet reached, and no "mysterious gas" has been reported. Soundings of the free air have established the fact that up to the greatest height attained by an aeroplane, about two miles, the composition of the atmosphere is sensibly the same as at the ground. However, some of the fatalities occurring can not be explained by mechanical defects, gusts of

wind, or "air-holes." Might not the "ethereal asphyxia" be similar to the drowsiness experienced by certain people in windy weather? Persons who have climbed to the summits of high hills or mountains often express a desire to lie down and sleep. Moreover, the cold aloft is another factor to be considered. One traveling in a balloon experiences a perfect calm about him and thus is not greatly affected by the low temperatures. But every one who has sat in the front seat of a rapidly moving automobile on which there was no wind-shield can readily imagine how chilling must be the air encountered by an aviator traveling against the wind. Even in mid-summer temperatures below freezing are met at a height of two miles, and such air, brushing past the aviator at a rate of a mile a minute, might soon cause temporary paralysis of the limbs, resulting in a loss of control of the craft. The heaviest clothing yet worn by an aviator could hardly give him the protection needed. Accelerated heart-action, nervous tension, fatigue and other factors doubtless contribute to the aviator's distress. The problem is not wholly a meteorological one.

SPECIAL ARTICLES

ON THE ORIGIN OF AN ALBINO RACE OF DEER-MOUSE

THE first case of Mendelian inheritance shown to exist among animals was that of total albinism in mice. In this condition the fur is snow-white and the eyes are pink, they like the fur being entirely devoid of skin-pigment. For the pink color of the eyes is due to the blood seen through the transparent eye; it disappears at death.

The ordinary white mouse is an albino variety of the common house mouse, with which it crosses readily. Cross-bred offspring (F_1) are never white, but like the wild parent in color. But in the next generation (F_2), part of the offspring are albinos. On the average one fourth are albinos, and these breed true in accordance with Mendel's law.

The time and place of origin of the common white mouse is entirely unknown; the same is true of nearly all distinct varieties of animals either domesticated or wild. Peculiar interest therefore attaches to a case in which an albino race has arisen from a wild species. Such a case I will now briefly describe.

The native field mouse of North America is known by several different common names, such as deer mouse, field mouse, white-footed mouse and wood mouse. Systematic zoologists at the present time give it the generic name *Peromyscus*. The most recent and exhaustive study of this genus is that of Osgood¹ (1909), who, after examining over 27,000 specimens from all the great collections of America and all other available sources, "conservatively" recognizes 157 distinct species and subspecies.

In the light of this exhaustive study it seems probable that *Peromyscus* is the most abundant and the most widely distributed of North American mammals, as well as one of the most carefully studied from the systematic standpoint. Nevertheless an albino specimen has never up to the present time been reported, which would seem to indicate that its occurrence is very rare.

In the fall of 1909, Mr. K. S. Clark caught in the woods near St. Johns, Clinton County, Michigan, a pure white albino *Peromyscus*. This he kept alive for some weeks and then delivered it to Professor Walter B. Barrows, of the Michigan Agricultural College, where Mr. Clark was a student. Fortunately neither Mr. Clark nor Professor Barrows obeyed the common impulse straightway to make a museum specimen of the rare individual. They tended this unique animal with great care. Later through the kindly interest of Professor W. M. Barrows, of Ohio State University, who was engaged with me in breeding experiments with *Peromyscus*, the albino was sent to me. I received it in Feb-

ruary, 1911, and kept it alive at my house or at the Bussey Institution until January 29, 1912, when it died probably from extreme cold.

In March, 1911, Mr. Clark trapped a dozen other *Peromyscus* near the place where he had caught the albino the previous fall, and sent these to me. All were normal in appearance and referable to *Peromyscus leucopus noveboracensis* Fischer, as described by Osgood. Two of the females were successfully mated with the albino which proved to be a male. During the summer and fall of 1911 they produced 6 litters of young including 28 individuals, all normal in appearance like the mothers. One of the daughters was mated with the albino father in October, 1911. On November 21 she bore a litter of three young, an albino and two ordinary young, but all were eaten the following night. Three weeks later she bore a litter of four young, two being albinos and two normal. The albinos were successfully reared, but no more young have since been born, and as this species does not breed in winter it is not probable that more will be obtained for some months.

The behavior of the albino variation thus far is that of a simple Mendelian recessive, as in house mice, guinea-pigs, rabbits and rats. The experiment has not yet progressed far enough to show whether the albino variation has been attended by variation in any other pigment factor, and so its continuation is awaited with interest. In the other rodents mentioned we have not only albino varieties, but also black ones (lacking a ticking or "agouti" factor), in all except rats yellow ones (with a reduced amount of black), and in mice and guinea-pigs brown ones (lacking black entirely). As nothing is known concerning the origin of these variations, it is uncertain whether they arose simultaneously with the albino variation, or as a consequence of it, or wholly independently of it. As, however, we find the inheritance of these variations to be wholly independent of the inheritance of albinism, it seems probable that in origin also these variations were independent. A case in which observation along these lines is possible is heartily welcomed.

¹ Osgood, Wilfred H., "Revision of the Mice of the American Genus *Peromyscus*," Publication of U. S. Department of Agriculture, Bureau of Biological Survey, N. A. Fauna, No. 28, 285 pp., 8 pls., Washington, 1909.

Men who make a business of producing plant novelties, Burbank, for example, are delighted with the slightest indication of sporting, because they consider that, the "stability of the type" having been disturbed, other variations are likely to follow.

Whether there is any basis of fact for this idea cases like that here described may tend to show, if carefully followed up. If the supposed phenomenon is found to be a real one and an initial color variation is frequently followed by others, then it will remain to discover an explanation, since "instability of type" can scarcely be regarded as an explanation, but only a figurative statement, of a phenomenon observed.

Studies of the inheritance of albinism, as already stated, show it to be independent in transmission of the several factors which determine the particular character of the pigmentation, as gray, black, yellow, etc. For in crosses with colored varieties, albinos actually do transmit to their offspring particular qualities of pigmentation, as gray, black, yellow, etc. It is assumed, therefore, that in the albino variation something has been lost from the organism which is indispensable to the production of pigment, though it has nothing to do with controlling the particular sort of pigment which the organism can form. Albinos, therefore, can be produced of as many different sorts as regards their breeding capacity, as are the visibly different pigmented sorts. Each pigmented sort finds its counterpart among albinos, though all these albinos may look alike. A study of the progeny of an albino through two generations will serve to show with what particular colored variety it corresponds. Such a study has not yet been completed for the albino *Peromyscus*.

The albino variation, being a *loss* variation and recessive in nature, must have existed in both the gametes (the egg and the sperm) which produced the individual captured by Mr. Clark. Both the parents of that individual, accordingly, transmitted albinism and probably produced other albino young, if they had more than a single litter of offspring. But the survival of albino offspring in the wild

state would be exceedingly doubtful because of their conspicuousness and their defective vision. Yet the heterozygous brothers and sisters of the albino sports should themselves be at no disadvantage in the struggle for existence and should produce about 25 per cent. of albino young. Therefore we should not be surprised if the sporadic occurrence of albinism should continue in a locality where it has once made its appearance, as in Clinton County, Michigan. The naturalists of that region would perform a service to science by looking for and reporting future occurrences of albinism in field mice there.

In conclusion I wish to express my gratitude to Professor Barrows (father and son) for entrusting to me the experimental study of this interesting variation.

ORIGIN OF THE SEDIMENTS AND COLORING MATTER OF THE RED BEDS OF OKLAHOMA¹

SINCE the origin of the sediments and the red coloration of the Oklahoma red beds has long been the object of more than ordinary curiosity, it may not be out of place to briefly outline some of the results of a recent study of these deposits.

Previous workers have made known the fact that the light-colored sediments of the lower Permian rocks of Kansas become red in Oklahoma, and that the similar light-colored Albany beds of Texas redden on approaching Oklahoma. In the Texas reports Cummins hinted that a lateral transition of the Albany beds into the red rocks of the Wichita formation might not be impossible. Later he worked out this transition in detail.² Gould and

¹Published with the permission of the director of the Oklahoma Geological Survey.

²The leading recent articles bearing upon this subject are: Cummins, *Trans. Tex. Acad. Sci.*, for 1897, pp. 93-98. Gould, *Kans. Univ. Quart.*, pp. 175-177, 1900; *Amer. Jour. Sci.*, XI, pp. 185-190, 1900; *Trans. Kans. Acad. Sci.*, XVII, pp. 179-181, 1901. Adams, *Amer. Jour. Sci.*, XII, pp.

Adams first described the transition of the light-colored sediments of Kansas into the red deposits of Oklahoma and Adams made a reconnaissance in Texas. Later, Kirk traced the Wreford limestone into a red sandstone in Oklahoma. Beede suggested that the sediments of the red beds were derived from the Arbuckle-Wichita Mountain region, and Gordon made further studies of the Texas region.

During the past summer the attempt was made to take up the study of this transition in somewhat greater detail in order to discover more fully its nature and significance. The horizons of the rocks lying between the Neva limestone and the Wreford limestone, as represented in Kansas, and a part of the way, the Fort Riley limestone were studied. A trip to the Wichita Mountains was made to study the relation of the red beds to the Permian conglomerates. With the exception of a single reference this paper deals with the strata of the beds studied.

In tracing the limestones and shales of the basal Permian beds of Kansas southward into Oklahoma the relationship of the light-colored sediments to the red sandstones, red shales and red limestones of Oklahoma is clearly revealed. It is shown that some of the heavier ledges of limestone first become sandy along their outcrops in patches a few rods across. Farther south the sandstone areas increase in size until the limestone appears only in local areas in the sandstones and is finally wanting. Traced farther southward, the sandstones become deep red or brown with local areas of white. The decimation of the fauna sets in as the limestones diminish and the remains of life are not found far beyond the limits of the limestones. The shales become red very much farther north than do the sandstones, and are frequently more deeply colored. Some of the lower limestones become red before they change into sandstones. The sandstone ledges continue for some distance southward

as rather even, uniform beds, but farther on they are found to thicken and thin in a somewhat systematic manner.

Several ledges of sandstone frequently occur in a single section and where one of these ledges is found thickened the others are apt to be thicker than normal. Likewise they are all found to be thin over certain areas. The regions of thickening and thinning were found to be parallel belts lying north and south at right angles to the major drainage lines. Two of these belts together with an intervening region about eight miles across were studied. The sandstones thicken at the expense of the shales, sometimes eliminating them. In one instance a thin limestone was traced southwest into one of these zones. A sandstone twenty feet or more beneath the limestone thickens and rises above the limestone and practically unites with the sandstone some distance above it. The limestone seems to die out a few feet from the sandstone, but farther west the latter shrinks to its normal thickness and the limestone is present in its proper position with its usual characteristics.

In these zones of thickening which are frequently several miles wide, the sandstones are very irregularly cross-bedded and frequently ripple-marked, while the thickening is uneven. It would seem that these zones are opposite the mouths of streams which brought sediment into the sea, where the coarser materials were carried farther from the shore than opposite the inter-stream spaces. The irregular thickening of the individual beds may be due to current work, wave action and heaping into local dunes by the wind, though the action of the last factor is uncertain. The irregular bedding and ripple marks indicate a sort of littoral or very shoal condition for the deposition of the sandstones and shales.

As this interesting transition of sediments is traced still farther southward, we find, before reaching the latitude of Shawnee, that the sandstones become more abundant over the whole area, more lenticular, more irregularly cross-bedded and imperfectly lithified. In a single railroad cutting a thick lens of

383-386, 1901; *SCIENCE*, XV., pp. 545-546; XVI., p. 1029, 1902; *Bull. Geol. Soc. Amer.*, pp. 191-200, 1903. Beede, *Jour. Geol.*, XVII., pp. 710-729, 1909. Gordon, *Jour. Geol.*, XIX., pp. 110-125. Kirk, Third Bienn. Rep. Okla. (Terr.) Geol. Surv.

sandstone may fade into a soft sandy clay shale with the same bedding and structure as the stone itself and change back into a sandstone a few rods away. Most of the sandstones are so incoherent when freshly quarried that pieces two or three inches in diameter crush readily under foot. In many of the wells of the region the water is obtained in "quicksand." Most of the shales contain much fine sand and offer little resistance to weathering.

At their southern limit these red sandstones and shales are found to dovetail into the Permian conglomerates on the northern side of the Arbuckle mountains, while similar conditions obtain among the higher beds farther west where similar conglomerates occur on the flanks of the Wichita mountains. These conglomerates are largely composed of the fragments of the pre-Carboniferous limestones aggregating 8,000 or 10,000 feet in thickness flanking the mountains and at one time covering them. The solution of these limestones produces a red clay wherever the insoluble residue happens to remain undisturbed below the vegetable mold, and the disintegrating limestone conglomerates produce a more or less sandy red clay indistinguishable from some of the red bed sediments. Thus it seems not improbable that much of the material of the red beds in the region studied was derived from these thick limestones.

Considering all these phenomena, it is apparent that the transition of deposits from the Arbuckle mountains to the Kansas line is such as would be expected in passing from the mountains out into a shallow epicontinental sea.

That the solution of limestone produces red residual clays is well known. It is exhibited in the residual soils and clays of the limestone regions of the unglaciated part of the Mississippi Valley, Cuba, southern Europe and elsewhere. The clays thus derived and their coloring matter—the red oxides of iron—are minutely divided and when in suspension settle slowly, but little movement of the water being sufficient to keep them in suspension. This characteristic adapts them to

long transportation. The great thickness of the Arbuckle and associated limestones, and their former extent, over thousands of square miles of country where they are now removed or represented only by their upturned edges surrounding the mountains, seem to furnish an ample source of the coloring matter and a considerable amount of the clays of these lower Oklahoma red beds. The Gabbros, red granites and red porphyries of the Arbuckle-Wichita region also contributed their share of sediment to the red beds.

From these observations it would appear that the sediments of the lower red beds of Oklahoma were derived largely from the Arbuckle-Wichita Permian land mass and the coloring matter mainly from the solution of the limestones known to have been removed from it. It also seems probable that the sediments of the region studied, especially those some distance from the mountains, were deposited in very shallow turbulent water, or vast tidal beaches, inimical to life of all kinds, since they are void of fossils or even carbonaceous matter.

J. W. BEEDE

THE ENTOMOLOGICAL SOCIETY OF AMERICA

THE sixth annual meeting of the Entomological Society of America was held at Washington, D. C., Tuesday and Wednesday, December 26 and 27, in room 376 of the new U. S. National Museum building. The following papers were presented:

HERBERT OSBORN: *Faunistic Studies in Entomology.*

The need of an extended and accurate record of insect fauna is urged, with statement of instances where such data have been much needed. Attention is called to the possibilities for widely scattered workers to assist in such studies and the desirability of some connected plan by which to encourage and bring together the results of such studies. A suggestion is made that the society appoint a permanent committee on faunistics, the duty of which will be to devise means for the encouragement of faunistic studies and to bring together the correlated results in this line with reports to the society as to methods proposed and the results secured.

E. P. FELT: *Numerals as Aids in Classification.*

The habitual use of numbers in catalogues indicates utility. A modified system of decimal notation is adapted to the needs of naturalists, while additions require little change. A general agreement upon the numbers for the major zoological division is suggested prior to the application of the system by cataloguers and other general workers.

E. S. TUCKER: *Studies of Insects Bred and Collected from the American Mistletoe.* Presented by Andrew Rutherford.

By the name of "American mistletoe," the species *Phoradendron flavescens* Nuttall and its several varieties is meant. Two snout-beetles belonging to the same group as the cotton-boll weevil were bred from terminal enlargements of the stem. From the larvæ of one of these beetles five hymenopterous parasites were bred, all of which attack the larvæ of the cotton-boll-weevil. About sixty species in all were obtained.

H. C. SEVERIN: *The Influence of Temperature on the Moulting of the Walking-stick, Diaphanera femorata.* Read by title.

R. MATHESON and C. R. CROSBY: *Notes on Aquatic Hymenoptera.* Illustrated. Presented by C. R. Crosby.

Three species of aquatic hymenopterous egg parasites have been reared at Ithaca, N. Y.: (1) a trichogrammid from the eggs of a damselfly (*Ischnura* sp.); (2) a proctotrupid from the eggs of a water strider (*Gerris* sp.); (3) a mymarid from the eggs of a back swimmer (*Notonecta* sp.). All of these forms are able to swim actively under water by means of their wings. They are also able to use their wings for flight in the air.

ANNA H. MORGAN: *Photographs Illustrating the Life Histories of May-flies.* Illustrated.

Photographs were shown which illustrated the life history and biology of about twenty-five May-flies. Both nymphs and adults were photographed alive; the nymphs in a solution of chlorotone, the adults without anæsthetic. Nymphs representing the main biological groups were shown and their habitat described. Imagoes and subimagoes of certain genera were shown and their structure and characteristic postures noted.

H. Y. TSOU: *The Chinese Wax-scale, Ericerus pe-la.* Illustrated.

One of the most beneficial insects of the family Coccidæ has been domesticated by the ancients of the Chinese people for the wax which it produces. This paper consists of (a) correction of errors of

European translations from Chinese works; (b) additional statements on the life history of the insect; (c) method of propagating this insect; (d) division of labor in carrying on this industry among the people of different localities, so that the eggs of the insect are produced in the northern district and the wax in the southern district; (e) importance of this industry; and (f) use of the wax.

A. D. MACGILLIVRAY: *The Lacinia in the Maxilla of the Hymenoptera.* Illustrated.

The Maxilla of *Macrozygela*, one of the most generalized of Hymenoptera, has the lacinia well developed. The lacinia among the wasps is a well-marked, triangular lobe attached to the distal and mesal end of the stipes. The maxilla of the Apoidea is greatly elongated for sucking, the galea enlarged and the lacinia reduced. The lacinia is a rounded lobe fringed with setæ and occupying the same position as it does in *Vespa*. It is not wanting or united with the galea in the honey-bee, as is usually stated in text-books and works upon apiculture.

LUCY WRIGHT SMITH: *Glycogen in Insects, especially in the Nervous System and the Eyes.* Illustrated.

In a heterogeneous lot of insects, including representatives of seven orders, glycogen has been found: (1) in immature and adult stages (a) in the crystalline cells of compound eyes, (b) in the crystalline and retinal cells of simple eyes, (c) in the neurilemma; (2) in immature stages only, (a) in the cells of ganglia in all parts of the body. No glycogen has been found in nerve fibers.

J. A. NELSON: *Note on an Abnormal Queen Bee.* Illustrated.

This queen was originally sent from Grand Bay, B. W. I. When received she was alive and quite active. It was planned to introduce her into a hive to test her fertility, but she died by accident before this was done. The dead queen appeared normal in structure with the exception of the abdomen, which was ovoid in shape, instead of conical as in the normal queen; it was also flexed strongly ventrad at the apex, which had consequently a blunt appearance, like that of the abdomen of the drone. The sternites of the 5th and 6th abdominal segments were unusually broad and somewhat asymmetrical, as was also the sternite of the 4th segment. The sternite of the 7th segment was the most modified of all, being greatly shortened in the longitudinal axis, and almost concealed by the sternite of the preceding segment.

The notch on its posterior border was abnormally broad and deep. The sting had a slight kink midway of its length.

The internal organs were apparently normal with the exception of the genital organs. The left ovary and oviduct were entirely wanting. The right oviduct and ovary were present, but the latter appeared to possess only a single egg tube. The spermatheca was empty. The bursa copulatrix was also shortened in the longitudinal axis, so that the external openings of the spermatheca and the poison glands were brought close together. No characters suggestive of hermaphroditism were found. The cause of the abnormalities is unknown.

J. CHESTER BRADLEY: *The Designation of the Venation of the Hymenopterous Wing*. Illustrated.

In the higher Hymenoptera, owing to certain remarkable conditions that prevail, the full application of the Comstock-Needham system of venation becomes a very complex matter. This is especially true in the case of the hind wings. By certain simple abbreviations this complexity is avoided, and the system becomes quite conveniently usable for taxonomic purposes.

ANN H. MORGAN: *Homologies in the Wing-veins of May-flies*. Illustrated.

The main tracheæ of May-flies precede and constantly mark the course of the main veins. The costal and subcostal tracheæ are simple, as are the veins which follow them. The radial trachea (except in one form) and the vein which follows it are unbranched. The radial sector is very probably present in May-flies, but in an unusual position between the veins M_1 and M_2 . It is detached from radius as in the dragon-flies and stranded upon M_1 . The medial vein has its characteristic four branches. This interpretation involves important changes in the nomenclature of radius and media.

A. D. MACGILLIVRAY: *The Pupal Wings of Hepialus thule*. Illustrated.

The adult wings of *Hepialus* are very similar to the hypothetical type of Comstock and Needham. The pupal wings show several features wanting in the adult wing. There is a two-branched subcosta, the first branch of subcosta disappearing and the subcosta of the Lepidoptera is therefore Sc_2 . The radial and medial tracheæ enter the wing through the same vein, the media together with a cross-vein forming the arculus between radius and cubitus. The presence of an arculus has not been reported in the Lepidoptera hitherto.

J. CHESTER BRADLEY: *The Wing Venation of Chalcid Flies*. Illustrated.

The hymenopterous family Chalcididae present a uniform excessive reduction in the number of their wing veins which is approached elsewhere in the Hymenoptera only by certain Proctotrypidæ and Evanidae. This depletion is the result of a degenerative tendency that is manifest wherever there is considerable reduction in the size of the wasp. It is of interest to ascertain with what veins of other Hymenoptera the vein remnants in the Chalcid wing are homologous.

The so-called marginal vein is in reality the elongated stigma, the "post-marginal" is r and R_1 and usually bears on its anterior margin a spur of the base of R_1 .

Leucospis is our most generalized group of Chalcididae so far as its wings are concerned. The wings of Chalcididae show a close relation to those of Cynipidae, through *Leucospis* in the one group and *Ibalia* in the other.

F. M. WEBSTER: *Our Present Educational System in Relation to the Training of Economic Entomologists*.

The demand for trained men capable of engaging in entomological work has increased greatly, but the graduates of the colleges generally are not equipped for such work and must have a special training of one to two years before they are available. The author wishes to emphasize the necessity for training in related sciences, in modern languages, and especially in field observation in entomology. The student intending to be an entomologist should begin in his first year with field observations and should be required to gather his own material for study. It would be especially desirable that students training for entomological work should have an experience at least during their vacations in work in some experiment station, and this sort of work should very properly be given credit in the college or university as part of the requirements leading to a degree.

C. W. JOHNSON: *The Use of Color in Designating Types and Varieties*.

Colored labels for types is being carried to an extreme. At the last meeting of the Cambridge Entomological Club one of our members who makes a specialty of printing labels for entomologists, asked me "what is an allotype, a homotype, a metotype, an autotype and a topotype, and why don't they use the same color for the same kind of a type? One wants his paratype on light

green, another on pink and a third on brown. Why I can't get enough colors to go around." An energetic collector with time and money at his disposal can make some sort of type out of seventy-five per cent. of his species. These various types may have some value, but they can not always be depended upon. A great number of colors used indiscriminately is very confusing, for there are equally important features that might be designated by color, aside from manufactured types. Colors could be used to advantage to indicate abnormalities, especially to-day when the experimental biologist is after data as to the number and kinds of abnormalities that occur in specimens in nature. Such specimens are completely overlooked unless they are marked in some way. Not more than two colors should be used for types: red for the primary, and green for supplementary types. Then another color, yellow, for instance, could be used for abnormalities.

HERBERT OSBORN: *A Problem in the Flight of Insects*.

Insect flight has been explained continuously by the movements of the wings vertically, the rigid anterior border with flexible hinder portion of the wing serving to so relate itself to the atmosphere as to furnish a forward movement. While this explains readily the forward progression, it does not in itself explain the hovering or the backward flight of many insects which is a matter of common observation. Numerous instances cited illustrate this feature. The explanation suggested for this movement is that the wings are rotated forward until the flexible under-portion of the wing reacts upon the atmosphere in such manner as to maintain the insect in a stationary attitude or even to propel it in a backward direction. Such rotation may be seen to be amply provided for in the structure of wings and the close observation of insects in hovering indicates the forward rotation.

E. P. FELT: *The Biology of Mistor and Oligarces*.

The widely distributed *Mistor* larvæ reproduce by pedogenesis in the moist, decaying bark of various trees during fall and spring, midges appearing from June till August. A larval generation occupies three to three and a half weeks. *Oligarces* is less common than *Mistor*. Both are subject to attack by a number of natural enemies.

LEONARD HASEMAN: *Entomological Work in Missouri*.

Since the early masterly work of Dr. C. V. Riley the entomological needs of Missouri have not been

properly served. Every line of entomological work is open for study. This department is investigating the more urgent insect problems of Missouri, though it is much handicapped by lack of assistance. The work connected with the instruction, station, nursery inspection and duties of state entomologist is more than the present staff can properly handle.

W. L. W. FIELD: *Hybrid Butterflies of the Genus Basilarchia*.

Since the Boston meeting two years ago, considerable progress has been made in the experiments with the supposedly hybrid *Basilarchias*, *B. proserpina* Edw. and *B. arthechippus* Scud. Their hybrid nature has now been proved by breeding experiments. The data obtained also support the conclusions drawn from earlier experiments, to the effect that in *proserpina* the black of *astyanax* is incompletely but uniformly dominant over the white-banded condition of *arthemis*.

The following annual public address was given at the Cosmos Club, Wednesday evening, December 27:

J. H. COMSTOCK: *The Evolution of the Webs of Spiders*. Illustrated.

It is probable that the production of silk by spiders was not primarily evolved for the making of webs for capturing prey. The representatives of many families do not spin webs; and there is no reason to believe that these non-web-making families have descended from web-making forms. All spiders use silk in caring for their eggs; and it is probable that this was the primary use of silk in this group of animals.

Spiders having acquired silk for the protection of their eggs have utilized it for other purposes, of which the making of webs for capturing prey is but one, and probably not the next one in the sequence of the different uses of this substance. The acquiring of the habit of spinning a drag-line, the thread which most spiders spin wherever they go, doubtless preceded the making of webs. A spider spinning a drag-line would make a web if

by chance it moved about in a limited space as in some nook in which it had taken up its abode. In such a web insects would be trapped, and thus might arise the habit of building webs for the purpose of trapping insects. Many spiders spin simple irregular webs composed entirely of the drag-line silk. From this simple type was traced series of specializations leading to the different types of complicated webs. In the making of some of these several different kinds of silk are used.

The following officers were elected for the year 1912:

President—Stephen A. Forbes.

First Vice-president—A. D. Hopkins.

Second Vice-president—C. P. Gillette.

Secretary-Treasurer—Alex. D. MacGillivray.

Additional Members of Executive Committee:

J. H. Comstock, J. B. Smith, Henry Skinner, Herbert Osborn, E. D. Ball, P. P. Calvert.

Member of Committee on Nomenclature—II. T. Fernald.

The society adjourned to meet with the American Association for the Advancement of Science at Cleveland, Ohio.

ALEX. D. MACGILLIVRAY,
Secretary-Treasurer

SOCIETIES AND ACADEMIES

THE ACADEMY OF SCIENCE OF ST. LOUIS

THE meeting of the Academy of Science of St. Louis was held at the Academy Building, Monday evening, January 15, 1912, President Engler in the chair. Dr. Arthur E. Ewing presented an illustrated account of *Sanninoidea exilis* (Say) and *Sanninoidea opalescens* (Hy. Edwards).

After describing the varieties of the *S. exilis* and the difference between them and the *S. opalescens*, giving the history of the insects and Beutenmüller's classification, examples were exhibited of the eggs on the bark of the tree, on the gum from the base of the tree, on leaves from the lower limbs of trees, and one on a trumpet vine leaf that grew a foot from the base of a tree, all of which were observed as they were laid and immediately collected, the collection having been made at the Mountainboro orchard, Mountainboro, Alabama, and at Gadsden, Alabama, between the first and the fifth of September, 1911. The exit of the larvæ from these eggs was observed to be from seven to nine days, the time of the one laid on the trumpet vine was eight days.

For four successive seasons the life period of

the insect had been carefully noted at Mountainboro, and it was found to confirm for northern Alabama the observations of Porter, Starnes and Sherman for Georgia and North Carolina, and shows that in the Southern Allegheny peach belt pupation begins about the first of August and the moth appears the last week in the same month. In 1908, August 4, as many full-grown borers were captured in this orchard of 15,000 trees as there were cocoons, the total number being 1,100; August 7, 300 cocoons were captured and as many borers destroyed. The same conditions obtained during the first week of August, 1909. In 1910 the investigation was made later and resulted in the finding of 8,500 cocoons between the 20th and the 24th of August and very few borers. Two hundred of the cocoons were placed in a wire cage on a southern covered porch. From these 25 moths emerged previous to September 5, 46 between the 5th and the 8th inclusive, 29 between the 9th and the 13th, and after this only two, one male the 16th and another the 21st. The remainder failed to develop.

Observations on the moths in the cage were that their activity depends greatly upon the temperature; with it below 70° F. they are very quiet, and very active when it is above 80° F. At night they sleep with their antennæ spread rather wide, some with the wings moderately spread, usually, however, with the wings near the body as when at rest, and the male with the tip of the abdomen strongly turned upward. When awake and alert the antennæ were erect and near together as if indicating the facial expression of the insect. At night they took no notice of an electric light right above them when it was turned on and off. Thus caged they lived only three or four days.

The 28th of August, 1911, fifty infested trees were examined. From the half of the cocoons the moths had escaped. During the examination only one borer was found which had not yet begun its cocoon. Throughout the orchard the moths were numerous, and in greater numbers from the 1st to the 5th of September. On September 13 only one moth was found, although a careful outlook was kept during the middle of the day, the time when the imago is most active.

An exhibition was made of the larvæ at numerous ages, from the emergence from the egg to the time of spinning the cocoon, together with an example of their destructive work on the tree, and numerous mounted examples of the male and female moth of the *S. exilis* type.

Also a cocoon was shown filled with the larvæ

of *Bracon mellitor* (Say), and others filled with the cocoons of this ichneumon, the parasite having been found in from one to two per cent. of the *S. exilis* cocoons examined.

Particular stress was laid upon the fact that only black and white drawings of the insects were given in the various state and national bulletins which were distributed throughout the country for the instruction of the orchardist, and lantern slides were shown from the plates of Beutenmüller in which there were at least 75 other examples of *Sesia*, which in black and white would readily be confused with this one by the laity. To be of any real value to the people all government bulletins dealing with insects should contain exact colored plates of the insect described in order to be intelligible to those not familiar with entomology. As an example, the owners and the foreman of the Mountainboro orchard did not know the *S. exilis* until they saw it emerge from the cocoon, although all of them had carefully read all the important government bulletins on the subject, particularly those of Slingerland, Marlatt and Starnes, and they had owned and cared for the orchard for more than ten years. As the moth flies only in mid-day, it was unquestionably often seen by them without being recognized.

GEORGE T. MOORE,
Corresponding Secretary

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

THE 455th regular meeting of the society was held October 24, in the new National Museum. The first paper read was by Mr. J. Mooney, on "Indian Survivals in the Carolinas."

He gave a brief account of his summer's work with the eastern Cherokee on their reservation in the mountains of western North Carolina, and with some mixed-blood survivors, locally known as Croatan Indians, in the eastern part of the state. The Eastern Cherokee, numbering about 2,000, are descendants of those who fled to the mountains when the body of the tribe was removed to the Indian Territory in 1838. They still retain most of their aboriginal customs and beliefs, together with their language, although the larger tribal ceremonies are nearly obsolete.

The Croatans, so-called from an attempt to identify them with Raleigh's lost colony of 1585, are centered chiefly in Robeson County, to the number of about 8,000 according to the last census, with bands in adjoining counties and in South Carolina. They appear to be descendants of the original native tribes of the same region, largely mixed

with alien blood, the Indian blood still predominative, although they have completely lost all knowledge of Indian customs, language or tribal names. They are intelligent and prosperous people, farmers and small tradesmen, fully up to the level of their white neighbors. They have official recognition from the state as Indians, with a separate school appropriation and support of a small paper called the *Indian Observer* devoted to their interests.

Mr. Hodge gave an exhibition and talk on the speech and civilization of the seventeenth and eighteenth centuries in New Mexico. Dr. P. Radin spoke on "Some Archeological Problems of the Winnebagoes." Dr. Hrdlička suggested that the physical anthropology of the skulls found in the Wisconsin mounds should be taken into consideration by the speaker.

THE 456th regular meeting of the society was held in the new National Museum, November 14. The speaker of the evening was Mr. W J McGee, on "Conditions Limiting the Growth of Population in United States." His talk was an elaboration of his paper in *SCIENCE* (October 6, 1911, pp. 428-435).

THE 457th regular meeting of the society was held in the new National Museum, January 16. The speaker was Dr. J. W. Fewkes, who lectured on the "Western Neighbors of the Prehistoric Pueblos," illustrating his remarks with lantern slides. The early Spanish discoverers, he said, designated the habitations of the sedentary Indians of the southwest by several names, as pueblos, casas grandes, rancherias and trincheras, the word pueblo being especially assigned to a compact several-storied community house of terraced form represented most abundantly along the Rio Grande River. The large houses on the Gila they called casas grandes, and they gave the name rancherias to fragile-walled dwellings made of brush and clay supported by logs. Defensive walls were sometimes called trincheras. Each of these names indicates distinct architectural types, although they were not used with accuracy. In late years it happens that all ruined buildings of the southwest, especially those independent of cliffs, are called pueblo ruins, the culture of the people that once inhabited them being designated the pueblo culture. It is well to preserve the term pueblo for the crowded-terraced many-storied buildings to which it was originally applied, and when this is done the distribution of the pueblo

type in our southwest is considerably restricted. The stone ruins ascribed to the ancient sedentary inhabitants of Arizona from the Upper Verde River west to the Colorado are not true pueblos. In this region there predominated massive stone forts of magnitude and fragile-walled houses with stone foundations, a duality everywhere evident. The indications are that both kinds of buildings were constructed and used simultaneously by the same people. The forts, situated on almost inaccessible hill tops, were asylums for safety, and more perishable buildings on the river terraces were habitations near aboriginal farms. The great number of these forts on the western border of the pueblo region implies a great necessity for defense along the whole western border of Arizona and Sonora in Mexico.

Dr. Fewkes gave a brief account of the different forts and terrace dwellings on the Upper Gila and its tributaries, Sycamore and Granite creeks, the Chino and Williamson valleys and Walnut Creek to the mouth of the Santa Maria and other tributaries of the Colorado, all examples cited substantially agreeing in the duality of architectural type and the absence of true pueblo structure.

The simple construction of the forts and the rude character of the masonry made of undressed stone, without mortar, was referred to. Views of the remains of dwellings or rancherias on the river terraces were shown and commented upon. Terrace sites indicated by rectangular and circular rows of stones and low mounds occur all along the Chino and Walnut valleys to Aztec Pass. These show no evidences of kivas or sacred rooms, or many-storied dwellings. The pottery found near them is rude, sometimes decorated; the pictography is characteristic; the people made extensive irrigation ditches.

The most important forts mentioned were those on the Upper Verde, near del Chino, and on the limestone ridge west of Jerome Junction. Two important forts (one situated near the mouth of Walnut Creek and the other at Aztec Pass, the latter being the "pueblo" first described by Wheeler) were referred to by the speaker. Maps of the Walnut Creek region are defective, the most prominent elevation, Mount Hope, being wrongly located on some of the latest issued by the land office. Big Burro and other streams west of Aztec Pass have forts overlooking enormous canyons of great scenic interest.

The geographical distribution of the forts and trincheras in western Arizona corresponds in a general way with the northern extension of the

Yuma stock, according to Major Powell's linguistic map. The country west of the Verde Valley in which the ruins occur was peopled by Yavapai, Hualapai, Havasupai, and other Indians called by Cortez, Apaches. The Havasupai, who now live in the depths of the Cataract Canyon, and the Hualapai are said to have legends that their ancestors constructed some of the buildings considered. The Hopi Indians dwelling in the pueblo Oraibi claim that certain of their clans came from the west and that they are of Yuma stock. The question of the kinship of the ancient builders is of interest to the physical anthropologist as well as to the linguist and student of culture history. As the Indians of the Yuman stock formerly extended to the Pacific, the possible kinship of the western neighbors of the pueblos to tribes of Southern California is significant.

Dr. Aleš Hrdlička in discussion said that the results of the direct study of man himself in the region west of the pueblos agree in a large part with the conclusions arrived at by Dr. Fewkes, but in part they also differ. It is quite possible that the region about and west to southwest of the Aztec Pass was once occupied by either the Mohave or Yuma. The people against whom they had to defend themselves, however, were more probably the Apaches. The Walapai and Suppai, who to-day speak the Mohave language, are physically Apache, and the same is true of the Yavapai. As the Apache type is a very distinct one, this conclusion is quite definite. Both tribes contain, of course, some Mohave and probably also Pueblo admixture.

Dr. Hrdlička showed a series of views of special Suppai and Walapai huts which are related to those of the Apache but which are totally distinct from those of the Mohave and Yuma, and numerous types of men and women from the several tribes, showing great resemblance between the Walapai and Suppai and the Apache, while the Mohave resemble much more closely the pueblos.

Mr. George Stetson then spoke on the Code of Hammurabi. His remarks showed how humanitarian the code was, and what an advance it was on Roman law in several respects, though antedating the latter by centuries. The speaker also demonstrated how the laws of various states of the union and certain foreign nations might well be advantageously amended on the lines of the code under discussion.

THE Society of American Bacteriologists stands, primarily, for pure as distinguished from applied bacteriology. In these days when the applications of the science are becoming so immensely important, and therefore so enticing to the investigator, there is danger that our thoughts turn not often enough to the broader aspect of the science, upon which, as a foundation, all of its applications must ultimately rest. We as a society must make it our special duty to see that these foundations are laid broad and firm, upon the very bed rock of truth itself.

We have as a society been interested for some time in the preparation of standard and uniform methods of describing bacterial species. This is of fundamental importance, leading as it does to uniformity of method and completeness and comparability of results. When we couple with this the use of the standard methods of the laboratory section of the American Public Health Association we have gone a long way toward the standardization of our work, and have begun the foundation upon which can be built the science of pure bacteriology.

But we must ever beware that we become not slaves to standardization and uniformity. It is well enough to proceed by standard methods, but we must not be tied by them. We must ever be ready to abandon the old and adopt the new, when the new marks the way of progress.

¹ President's address before the Society of American Bacteriologists at the Washington meeting, December 28, 1911.

At this time I wish to bring to your attention some of the lines along which we are making little progress, I believe, because of the false security which we are taking in our standard methods.

First, suppose we consider our ordinary culture media. We have drawn up ridiculously exact procedures for mixing and boiling and filtering and titrating our broth, agar and gelatin, and when we are through we believe we have a standard, uniform product. But indeed it is not so. Not only are the results obtained in different laboratories unlike, but two lots of the same medium made at different times in the same laboratory are extremely unlike, when measured by the delicate physiological properties of organisms which respond to the slightest of chemical differences. Far better, it is true, are the results secured at the present time by the use of standard methods, than before their introduction, and I do not for a moment want to decry our standard methods, but I simply want to warn against the false security which their use may give. For however careful we may be in the process, the final result can never be uniform as long as the ingredients used are themselves variable. No medium can be standardized, that is, can be exactly duplicated at another time or place, if it contains such variable materials as beef extract, either freshly made or commercial, peptone, gelatin, agar, blood serum, bile, etc. I am inclined to think that in order to get uniform results, particularly in our study of the delicate physiological properties upon which we depend so largely for the differentiation of bacterial species, the time has come for us to abandon altogether the use of all complex and variable animal and vegetable products, and in their places to substitute materials of definite, known, chemical composition. From my work of

the past few years I am led to believe that for every organism it is possible to prepare a synthetic medium containing chemically pure salts, upon which these organisms will grow and grow well. Such a medium as this we are able to duplicate exactly anywhere and at any time.

In the past we have been inclined to think that the physiological properties of many organisms were too variable to be of much use in species determination. I am coming more and more to think that it is not so much the properties of the bacteria which are variable as the environment in which we have attempted to study them. We talk about rejuvenation of organisms to restore them to normal conditions. Our attempts at rejuvenation are attempts to make normal organisms adapt themselves in short order to an abnormal environment. Could we but supply the proper environment we should find the organisms responding in an entirely normal and uniform manner. It is the environment, our culture media, that need rejuvenating and not the organisms. This rejuvenation will come about, I believe, through the adoption of synthetic media of absolutely known chemical composition. Then the physiological properties of organisms will come into their proper place in species differentiation, for then we can substitute the exact qualitative and quantitative tests of the chemist for the inexact determination of the present-day bacteriologist.

There is scarcely a physiological property of the bacteria that is to-day accurately measurable. Variations in the media are so great that measurements at present amount to nothing. Chemistry advanced to its present position as a science only when it became quantitative. Lord Kelvin said: that "When you can measure what you are speaking about, and

express it in numbers, you know something about it; but when you can not measure it, when you can not express it in numbers, your knowledge is of a meager and unsatisfactory kind; it may be the beginning of knowledge, but you have scarcely in your thoughts advanced to the stage of science." Bacteriology must then become quantitative before the real foundations of the science are laid, before it can take its proper place among the sciences. And it can not become quantitative until we can measure its reactions in media of known chemical composition, by methods as exact and definite as any known to the chemist. We are always dealing, it is true, with living protoplasm, but if we place it under definitely determined environment, recent experiments lead us to believe that living substance always responds in a perfectly definite way both qualitatively and quantitatively.

The very complexity of the society's card for the description of bacterial species is to me its own condemnation. It is our admission of ignorance. Are not the real diagnostic characters of a species lost in a maze of unessential characters? Aside from the morphological data, which I believe is all-essential, the cultural and biochemical data could, I am sure, be simplified to a very considerable extent as far as species differentiation is concerned. The forms of cultures and colonies are but functions of the morphology and methods of subdivision of the organisms themselves, as has been so well shown by the recent work of Graham-Smith.² We might then eliminate from the card many of the complex descriptions of cultures and colonies on agar and gelatin, retaining perhaps the agar streak and the gelatin stab, and sub-

stitute therefore information in regard to their determining factors. And then among the biochemical data if we could eliminate all but a few deep-seated physiological characters which are accurately measurable, and which can be easily determined by means of accurate chemical tests on synthetic media of known composition, we would have a simple, accurate, all-sufficient description of a bacterial species.

One of the weakest parts of bacteriology to-day is its taxonomy. Our methods of classification of bacteria are practically the same to-day that they were in the earliest days of the science. Migula, it is true, systematized the scheme of classification to a certain extent, Chester contributed to its more accurate terminology, and the Winslows gave it a new impetus by the introduction of the methods of biometry. But when we think of the thousands of described species among which but two or three genera are recognized, it must be apparent at once that some of our generic names are seriously overworked. In other biological sciences the classification into species, genera, families, orders, classes, etc., is not only of great convenience, but it also expresses for us something of the relationship of the different groups, something of their probable ancestry and line of evolution. I see no reason why the bacteria should not be classified in the same way. The bacteria are not exceptions to the general biological laws. Variation, selection, heredity, are the factors of evolution here as elsewhere. It is true among the unicellular forms we are free from many of the complications which enter into our discussions of the origin of species among multicellular animals and plants. Sexual reproduction is absent, there is no differentiation into germplasm and somatoplasm to prevent the acquisi-

² Graham-Smith, G. S., "The Division and Post-fission Movements of Bacilli when Grown on Solid Media," *Parasitology*, 3, 1910, 17.

tion of new characters, the environment presses very closely upon these unicellular forms and they respond more directly to it. Generation follows generation with startling rapidity, elimination of the unfit proceeds rapidly, the struggle for existence is more severe because of the enormous numbers concerned. In the bacteria we ought almost to be able to see the actual process of evolution since we can place under observation untold numbers of generations as compared with the comparatively few generations of multicellular forms which we are able to observe. Eons of multicellular time are literally compressed into a few unicellular days.

Because of this lack of the regulating influence of reproduction and the greater influence of the environment and the rapidity of reproduction, we might expect to find among unicellular organisms a series of intergrading forms without divisions into groups that resemble the species of higher forms. But this is not so. Among the protozoa differentiation has followed definite lines, and classes, orders, families, genera and species are well marked. The species of protozoa are, for the most part, based on morphological differences, it is true, but among the bacteria a morphological basis of classification fails us. The only morphological differences are the three main divisions as to shape, the round, the rod and the spiral, with slight modifications as to size, arrangement of flagella, formation of spores, chemical composition, etc. But in spite of this lack of morphological basis for classification we find as distinct groups as among the protozoa. As the Winslows say:³

Typhoid germs descend from typhoid germs, tubercle bacilli from tubercle bacilli. The same

yellow coccus falls on gelatin plates exposed to the air all over world. The same spore-forming aerobes occur in every soil, the same colon bacilli crowd the intestines of animals and man in every clime. These fundamental types can not be transformed into each other.

And yet to a considerable extent these fundamental types are based not on morphology, but upon physiological differences.

It is among the bacteria that for the first time among living forms we find physiological differences made a basis for classification. Are physiological properties valid criteria for the separation of species? We are accustomed to think of morphological characters as fairly stable, rather difficult to modify, but of physiological characters as easily modified and directly dependent upon the environment. But have we any reason to assume that physiological characters are not deep seated also, are not stable, fully as much as morphological characters? Are we not in reality dealing with characters of the same sort as morphological characters except that we can not see their ultimate basis in structure? I am not sure but what physiological characters are even of greater importance than those of form and external appearance, especially in such simple and undifferentiated forms as the bacteria, since they testify to deep modifications in the chemistry and vital properties of the protoplasm itself. It is upon such chemical properties as these that these simple organisms depend for their very existence, and not upon a modification of external appearance.

But before we can proceed far in the use of physiological differences for species determination we must be able accurately to determine these delicate characters. Hitherto this has been impossible because of the variable and uncertain culture

³ Winslow and Winslow, "Systematic Relationships of the Coccaceæ," p. 1, John Wiley and Sons, 1908.

media in which we have attempted to study them. With the adoption of media of definite chemical composition for making our determinations and measurements, the physiological characters of the bacteria will assume the importance of the morphological characters of higher organisms. Then and then only shall we be able to arrive at a natural classification of bacterial species which shall express for us their true relationship.

With the adoption of such accurate chemical tests of the physiological characters of the bacteria much of the present apparent variation will pass away and we shall find the physiological characters of the different groups as stable as any of their morphological characters. And what little variation remains—and we shall always find some variation as long as we deal with living organisms—we can handle easily by the method of biometry. For, as you know, the methods of statistical variation can apply only in characters which are measurable.

This matter of better methods of species identification and a new taxonomy will be one of the first outcomes of the adoption of simple chemical culture media.

Another important result will be the increased ease with which certain biochemical problems in bacteriology can be attacked. Think for a moment of our endeavors to find a suitable method of isolating the colon bacillus. Litmus-lactose-agar, endo, esculin, neutral red, malachite green, phenol, bile and bile salts and their various combinations are but expressions of our total ignorance of the chemistry involved. The problem should be attacked in an entirely different way. First, we should determine the simplest synthetic medium upon which the colon bacillus will grow rapidly and well. Then by adding to it the chemical body which is the in-

hibiting agent in the phenol or in the bile we ought to have the ideal medium for colon isolation. A beginning along this line has been made by Dolt⁴ in his ammonium lactate, glycerin and malic acid media. But further work must be done until we have a simple synthetic substitute for the complex, variable and inconvenient media upon which we depend so much at present.

And then take the differentiation of the colon and typhoid groups by cultural characters. There must be certain chemical differences inherent in these organisms which could be easily determined by the use of synthetic media adapted to each organism.

Another desideratum is a simple synthetic medium to be used as a substitute for blood serum when used for the diagnosis of diphtheria. We have to depend at present upon the uncertain and unsatisfactory supply of blood from the abattoirs. How much better would it be to find a chemical substitute which would be just as certain for diagnosis and much easier to prepare? I believe that such a substitute will soon be forthcoming.

We have been gradually accumulating a knowledge of a considerable number of important chemical products which are produced by the activities of bacteria either by synthesis or decomposition. Many of these substances are of great importance. Many are produced only as far as we know at the present time by bacteria. How little at present we know of the chemistry of these products! How much can be learned by a study of the formation of these substances in culture media of known composition! The chem-

⁴Dolt, M. L., "Simple Synthetic Media for the Growth of *B. coli* and for its Isolation from Water," *Journal of Infectious Diseases*, V., 1908, 616.

istry of ptomaine and toxin formation, of pigment formation, of enzyme production, may be worked out in this way. The chemist laughs at our present methods of testing the production of gas, the reduction of nitrates, the production of indol, the fixation of nitrogen. And yet when these processes are tested in synthetic media how simple are the chemical tests involved and how accurate may be the results!

Slowly and laboriously the physiological chemist is now trying to work out the chemistry of protoplasm, of the proteins, such as the albumens, the peptones and proteoses. His principal line of attack is by a study of their decomposition products. The brilliant work of Fischer opened up an entirely new field of research when he undertook the study of the synthetic production of the polypeptides from amino acids by an amide link. Still more light might be thrown upon this important problem by the study of the growth of bacteria in simple chemical solutions. For in the synthetic culture medium we would be able to study step by step the synthesis of protein under conditions accurately controlled and completely known. For when bacteria are growing on simple chemical media and are building up untold millions of bacterial bodies from the simple salts present, we can almost see protoplasm in the making.

And finally, aside from the important chemical information which may in this way be obtained, I believe that some most interesting biological information lies along this path. Who would dare to deny that some day it might be possible by some such method as this to discover the secret of the very origin of life itself!

These then are some of the lines of work which appear to me to mark progress in the science of pure bacteriology. Brilliant

as may be the results of the study of the applications of bacteriology, fully as interesting, and hardly less important, will be the results that come from the application of exact chemical methods to our at present inexact and rather uncertain bacteriological procedures.

F. P. GORHAM

BROWN UNIVERSITY

*THE TEACHING OF MICROBIOLOGY IN
COLLEGES OF UNITED STATES
AND CANADA*¹

In his admirable presidential address delivered before the Society of American Bacteriologists at the Ithaca meeting in December, 1910,² Professor V. A. Moore made a strong argument for bacteriology as a science for general culture as well as for professional value, and a vigorous appeal for better teaching and more carefully developed courses. As a result of this exposition of the subject a committee of this society was appointed to make a systematic inquiry into the teaching of microbiology, including bacteriology, protozoology and the study of the lower fungi, in the educational institutions of the United States and Canada.

The purpose of the inquiry is primarily to learn to what extent bacteriological instruction is given in these institutions, and secondarily to note the character of the teaching in these subjects and the scope of the work. It is possible that as a result of these data submitted the committee may be able to formulate a generally broad and satisfactory plan of instruction in this subject, although this is not the immediate purpose of the committee and it is possible that an attempt to do so would react harmfully in certain instances.

While it is hoped the inquiry will eventually embrace institutions of all ranks, the first report of progress presented at the Washington meeting dealt only with the colleges and

¹ An abstract from the first report of progress by the Committee on Education of the Society of American Bacteriologists.

² SCIENCE, N. S., Vol. XXXIII., No. 848.

technical schools. These may be classed as follows: (1) The colleges of arts and sciences leading in general to the A.B. or S.B. degree; (2) the colleges of agriculture; (3) the colleges of medicine; (4) the technical schools or schools of applied science.

At the outset it should be said that the report on the teaching in these institutions is far from complete, that many schools have not supplied information, and that the following statements form merely the beginning of what, it is hoped, will be a comprehensive and useful study.

The chairman of the committee early in the year prepared a set of questions which were submitted to the other members of the committee for suggestions and desirable changes. These were incorporated in the final list. These questions have been submitted to about 550 institutions of the rank as stated above in the United States and Canada. The collegiate institutions of Canada were not found in any list of the colleges available, but a list was obtained by direct application to the Canadian commissioner of education, to whom cordial thanks are extended. The questions were as follows:

1. What courses in bacteriology, if any, are given in your institution?
2. How many hours of lecture, recitation and laboratory work are devoted to each?
 - Lecture
 - Recitation
 - Laboratory
3. Is the subject a required one, or elective?
4. At what year in the college course is it given?
5. To what group (department) or groups of students is it given?
6. What preliminary training in biological sciences is required?
7. What preliminary training in physics, chemistry, mathematics and languages is required?
8. Is the subject presented as
 - (a) Part of a course in general biology or botany?
 - (b) As a general science course for its educational value?
 - (c) As a special or professional course in applied science?
 - (d) As a part of any other course? If so, what course and how extensively?
9. If more than one course is given, will you state the scope and character of each, and the approximate number of students in each?
10. If the courses are given from the applied science standpoint, are they given in their relation to
 - (a) Medicine?
 - (b) Public health?
 - (c) Dairying?
 - (d) Soil and agriculture?
 - (e) Industrial processes?
11. What is the character of the laboratory work actually performed by the students, *i. e.*, how elaborate experimentation do they actually do?
12. Are the students directed in what might be called research work in bacteriology, *i. e.*, advanced work and investigation, aside from ordinary routine class work?
13. What books do you use as text-books for the course?
 - As collateral reading?
14. What courses in protozoology are given?
15. What text and reference books used?
16. What courses devoted to other branches?

Replies have been received from 121 of these and it is on the basis of the replies received up to the present time that the following tabulations and statements are made. A second list of questions has been submitted to those institutions of the original list and supplementary institutions not on the original list from which no replies had been received up to December 21. The failure to reply undoubtedly means in certain instances that no courses are given or that there is no professor dealing with the subject in hand, and consequently letters have failed to be properly received, or there may have been oversights on the part of the professor in charge. Because of the possibility of the second alternative it has seemed desirable to send out the second set of questions.

The replies which have already been received in response to the circular have been of much interest, and careful study may be grouped into a number of tolerably definite classes. In general the replies indicate fairly clearly the scope of microbiological instruction, and in several instances there have been

submitted course schemes showing the exact range of subject matter presented.

On the basis of the study of these replies the chairman has grouped the institutions into several classes which I have characterized as follows:

Group I.—Those institutions in which some phase of the subject of bacteriology is presented very briefly, and in general avowedly from the standpoint of general education, or in connection with courses in general biology, botany or hygiene given from the culture rather than the professional standpoint. Some actual laboratory work is done, however.

In addition there is sometimes an intention to introduce the student to some phase of applied bacteriology in a very brief way. These brief courses vary much in character and extent, and this group is, therefore, the most difficult to classify. A few have made pretentious claims which obviously can not be lived up to in the courses given.

In many of these courses the plan of attack seems to be well thought out, and the relations of lecture and laboratory work is well calculated to give the student a fair general introduction to the whole subject. However, it is only an introduction, and the student product can not be regarded as a trained bacteriologist. On the other hand, some of the courses seem to be badly balanced, to give an undue weight to lectures and too little to laboratory work, and to emphasize some particular and rather narrow phase of the subject.

The institutions which I have included in this group are 39 in number and include for the most part the smaller colleges, or those having no highly specialized courses in applied sciences leading to a professional degree. These courses are apparently sometimes taught by instructors who have had no special or thorough training in bacteriological methods, but who have gained some knowledge of the bacteria, and who have introduced the work in the curriculum because of their personal interest in the subject or their ability to adopt such knowledge to supplement courses already given. In none of these institutions is there any attempt to carry on worthy investi-

gations or research, although in a few of the replies it has been stated that "investigations" are conducted. Examination of the type of research, however, shows it to be trivial and to consist generally in the microscopical examination or plating out of bacteria from a water supply, milk supply or some such simple source. The consideration of this group of institutions can not fail to impress the members of the society with some of the statements made by the president in his address last year, in which he put in a forceful plea for more scientific methods in teaching and more training on the part of those giving instruction in this important subject in many institutions.

Group II.—This group includes institutions having in general but one course or at most two separate courses, but in which work is conducted on broader lines, with more abundant laboratory work and generally in which the teacher is himself a trained worker in some field of bacteriological study and in close sympathy with the subject.

The courses here grouped may in some instances be described as presented primarily for the educational value of the subject as seen in a broad way, and are given from the standpoint of general culture and in the same spirit as that exhibited in the teaching of courses of general chemistry, general botany or general zoology.

Frequently after a fairly broad and comprehensive introduction the work is later restricted to some special phase of bacteriology, as soil, dairy, or sanitary work, so that the subject is actually given with the applied science end in view.

In this group there are undoubtedly some courses which are poor in the sense that they fail to give to the student a broad knowledge of the fundamental principles underlying bacterial behavior and activity. In other words, the biology of the bacteria as a group of living things is frequently subordinated to the examination of water for colon bacilli or the microscopical study of a few restricted types, such as the more common of the pathogens. On the other hand, many of the replies from

institutions which should be placed in this group indicate that bacteriological instruction is on a good foundation, and may be built up with comparative ease when opportunity offers.

In these institutions investigation work of a legitimate character is frequently conducted, and the best of the institutions of this class are contributing valuable work to the sum total of our bacteriological knowledge year by year, through their researches.

I have grouped 22 institutions in this class, in half of which, probably, work of high character is being carried out, while in the others the results do not appear to be so satisfactory.

Group III.—In Group III. I have brought together 28 institutions. In 25 of these, as appears from the catalogues or from subject matter presented in the reports, there is what may be called a well-rounded department of bacteriology or microbiology, with a central fundamental course in general bacteriology. Following this and dependent upon it may be found well organized courses in several of the applied branches, such as soil bacteriology, dairy bacteriology, sanitary bacteriology, fermentation work and medical or public health work. Twenty-five of the twenty-eight institutions here grouped present the breadth of work which I have just described. In three of them the work is organized with a somewhat less broad scope, but it appears to be evident that the work in these institutions is excellent as far as it goes.

Group IV.—In ten institutions, which are almost without exception medical departments or pre-medical courses, the work in bacteriology is arranged with one point in view, namely, to introduce to the student the more common of those types of microorganisms which are the causes of disease. It seems to me that the chief criticism to be made of these courses is that the student loses sight entirely of the important general relations of the bacteria to human welfare and is likely to regard the group simply from the standpoint of disease-production and never from the standpoint of industrial or economic value, or from the standpoint of general culture. In

all the institutions of this class, the work is carried out in the graduate department or in the school not connected with the university, and in the former case no serious attempt is made to interest undergraduate men in the subject at all.

Group V.—I have made a separate group for those institutions, schools of engineering, in which a smattering of bacteriology is given to civil or sanitary engineers, in order that they may more properly appreciate sanitary problems. This group is very small, replies having been received from but few institutions. In these the narrowest kind of instruction is given, and the matter is presented in such a way as to leave the impression with the student that deciding upon the sanitary condition of the water supply is a perfectly simple matter requiring no special training. For example, one of the institutions which reports having a class in water bacteriology, states that the number of lectures given in the subject is but four, the laboratory work of the three brief periods and consisting in the examination of but one sample of water and one sample of sewage for the total count and presumptive test for colon bacilli. In the opinion of the writer such courses do positive harm, because they give to the student a false sense of knowledge and ability to decide problems which may be of the utmost importance for the welfare of thousands of people.

The remaining replies may be all grouped in a class together. This includes eighteen institutions. In seventeen of these no real courses in bacteriology are given, although the informants have stated that brief consideration of the subject is taken up in connection with botany, physiology or hygiene. No laboratory work is done, however, and it is evident that these institutions do not require any special consideration. In one of the institutions here grouped, a brief course is given in the examination of bacteria, yeasts and molds, from the standpoint of household economics. The work, however, is very elementary in character.

While it is somewhat disappointing to receive replies from less than one fourth of the

institutions to which the sets of questions were sent, this possibly represents a fairly high proportion of institutions in which instruction in this subject is given. While I am certain that well-defined bacteriological courses are presented in several institutions from which no replies have been received, a survey of the institutions with which I am familiar would lead me to believe that the replies had come probably from a majority of the schools giving bacteriological instruction. From the standpoint of geographical distribution, it seems to be evident that the middle west has done more in the promotion of microbiological education by the installation of courses than has the east or the south. Practically all the central and western state universities and agricultural colleges seem to have well-defined courses, and since these schools occupy very prominent positions in the field of education in the west, it appears to be evident that the student of the central and western part of the country has a greater opportunity to take work in this subject than has the eastern student, who is more likely to attend the privately endowed institutions. New England, with approximately thirty-five colleges and technical schools has, outside of the purely agricultural colleges, but five institutions in which comprehensive bacteriological instruction is given to the candidates for the Bachelor's degree in arts or science. No definite courses are offered in the collegiate department at Harvard, Yale, Dartmouth, Williams, Amherst, Bowdoin, Columbia, Princeton, Pennsylvania or Colgate, and this list could, with a little consideration, be very greatly extended.

It does not seem to the writer that this is the time to suggest methods of instruction, or the exact ground which should be covered in microbiological subjects. It is, however, worth emphasizing that the proper interpretation of bacteriological problems can not be had until the instruction in bacteriology is placed upon a very broad biological and physiological basis, and until there are correlated with such courses training in physics, chemistry and mathematics. These correlated subjects

should be of sufficiently advanced character that the student may consider the organisms in their physical, chemical and biometric relations, for it must be admitted that modern bacteriology includes far more than the microscopical examination and cultivation of a few pathogenic types.

SAMUEL C. PRESCOTT

*A BOTANICAL-ZOOLOGICAL LABORATORY
IN PORTO RICO*

THE University of Porto Rico announces that it plans to offer to students facilities for research in botany and zoology in the American tropics.

Special space will be set aside in the agricultural building now in process of erection and the well-equipped physical, chemical, botanical, zoological, bacteriological and plant pathology laboratories may be drawn upon for supplies and apparatus. The research laboratories will be equipped only with the usual essentials, but endeavor will be made to meet special needs, in the way of equipment, which the problems of each student demand.

It is probable that a seaside laboratory, within a few yards of the ocean, will also be provided with needed equipment, including a motor launch for marine collecting, and that a third laboratory will be located on some suitable elevated region. These facilities will be extended to all who are competent to use them and are properly accredited by reputable institutions.

Free tables will be provided for a limited number of advanced students under conditions which will be explained upon communication with the director.

Students who desire to use the laboratories are requested to communicate, as early as possible, to the director, their needs and dates at which accommodation is desired, since there is often delay in procuring supplies.

For the information of prospective students, the following data are given:

Porto Rico lies between 17° 54' and 18° 30' north latitude. Geologically it is of much interest, though but little studied as yet. It is extremely rugged and picturesque with its

many volcanic peaks, some rising over 3,700 ft. Caves abound. The climate is delightful and healthful; the nights cool. The mean annual temperature is 76°, the average during the coolest winter month 73°, during the warmest month 79°. The early morning temperature averages 70° in summer, 63° in winter. The average daily maximum is 88° in summer, 83° in winter. The highest temperature recorded on the island last year was 99°. The highest at Mayaguez was 96°. Vegetation is beautiful, distinctly tropical and luxuriant.

The pelagic flora and fauna of the Mona passage are especially interesting. Trawls, dredges, aquaria, etc., will be provided. Fine opportunity is offered for the study of animal and plant anatomy, embryology, physiology, taxonomy, morphology, experimental morphology, ecology, climatic relations and breeding; tropical fauna and flora, marine and land, and problems on geographic distribution and bird migration.

Correspondence of all interested is invited. All who intend to come for summer study, or for other portions of the year, should write several months in advance.

F. L. STEVENS,
Director

SCIENTIFIC NOTES AND NEWS

THE lord provost of Glasgow proposes to convene a conference to promote an international memorial to Lord Lister in Glasgow.

FOR the meeting of the British Association for the Advancement of Science, which is to be held this year at Dundee, beginning on September 4, under the presidency of Professor E. A. Schäfer, F.R.S., the following presidents have been appointed to the various sections: Mathematical and Physical Science, Professor H. L. Callendar, F.R.S.; Chemistry, Professor A. Senier; Geology, Dr. B. N. Peach, F.R.S.; Zoology, Dr. P. Chalmers Mitchell, F.R.S.; Geography, Sir Charles M. Watson, K.C.M.G., C.B., R.E.; Economic Science and Statistics, Sir Henry H. Cunyng-hame, K.C.B.; Engineering, Professor A. Barr; Anthropology, Professor G. Elliot

Smith, F.R.S.; Physiology, Mr. Leonard Hill, F.R.S.; Botany, Professor F. Keeble; Educational Science, Professor J. Adams; Agriculture, Mr. T. H. Middleton.

PROFESSOR CHARLES SEDGWICK MINOT has been selected by the German government as Harvard exchange professor at the University of Berlin for 1912-13. Dr. Rudolf Eucken, professor of philosophy at Jena, has been appointed exchange professor at Harvard University.

DR. WILLIAM T. BRIGHAM, director of the Bishop Museum, Honolulu, has been made a corresponding member of the Imperial Academy of Science, St. Petersburg, and of the Senckenbergische Naturforschende Gesellschaft at Frankfurt.

THE following have been elected correspondents of the Academy of Natural Sciences of Philadelphia: Viktor Goldschmidt, Carlotta J. Maury, John Casper Branner and Charles Haskins Townsend.

PROFESSOR W. ODLING, F.R.S., of Oxford University, has resigned the Waynflete professorship of chemistry, which he has held for forty years.

PROFESSOR A. H. PURDUE, who for nearly sixteen years has held the chair of geology in the University of Arkansas, and since 1907 ex-officio state geologist of Arkansas, has been elected state geologist of Tennessee to succeed Dr. Geo. H. Ashley, resigned.

D. W. OHERN, professor of geology at the University of Oklahoma, has been appointed director of the Oklahoma Geological Survey to succeed Chas. N. Gould, who has resigned to enter private work.

MR. MYRON L. FULLER, a geologist on the U. S. Geological Survey, and Mr. Frederick G. Clapp, formerly of the survey, have organized an association known as the Bureau of Associated Geological Engineers with offices in Boston and Pittsburgh.

MR. E. NEVILLE NEVILL, director of the Natal Government Observatory, Durban, is retiring from office, and will in future live in England.

PROFESSOR J. A. GILRUTH, professor of veterinary pathology in Melbourne University, has been appointed administrator of the northern territory by the commonwealth government.

THE Liverpool health committee has recommended the city council to lend the city engineer, Mr. J. A. Brodie, to the government of India for the purpose of assisting in laying out the new capital of India.

PRESIDENT TAFT appointed the following scientific men on the recent Essay Commission: Professor John Trowbridge, of Harvard, Professor G. W. Stewart, of the University of Iowa, Professor O. L. Shinn, of the University of Pennsylvania, Professor R. C. Benner, of the University of Pittsburgh, Dr. M. Benjamin, of the Smithsonian Institution, and Dr. L. A. Fischer, of the Bureau of Standards.

THE Entomological Society of America has appointed Professor John B. Smith, Rutgers College, Dr. L. O. Howard, chief, Bureau of Entomology; Dr. E. P. Felt, New York state entomologist; Dr. W. M. Wheeler, Harvard University, and Dr. W. E. Britton, Connecticut state entomologist, as delegates to the centennial of the Philadelphia Academy of Sciences, to be held on the 19th, 20th and 21st of March. Professor George Grant MacCurdy will be the delegate from the Paris School of Anthropology.

THE anniversary meeting of the Geological Society of London was held on February 16, when officers were appointed as follows: *President*, Dr. A. Strahan, F.R.S.; *vice-presidents*, Professor E. J. Garwood, Dr. J. E. Marr, F.R.S., Mr. R. D. Oldham, F.R.S., and Professor W. W. Watts, F.R.S.; *secretaries*, Dr. A. Smith Woodward, F.R.S., and Mr. H. H. Thomas; *foreign secretary*, Sir Archibald Geikie, K.C.B., president R.S.; *treasurer*, Mr. Bedford McNeill. The following awards of medals and funds were made: Wollaston medal, Mr. Lazarus Fletcher, F.R.S.; Murchison medal, Professor Louis Dollo; Lyell medal, Mr. Philip Lake; Wollaston fund, Mr. C. I. Gardiner; Murchison fund, Dr. A.

Morley Davies; Lyell fund, Dr. A. R. Derryhouse and Mr. R. H. Rastall.

DR. SVEN HEDIN is planning a new expedition to Asia.

AN expedition to Newfoundland will be conducted next summer by Professor R. S. Tarr, of Cornell University, to which a limited number of students will be admitted. The geology and physiography of the island will be studied in the field. The party will carry its own camping equipment.

PROFESSOR RAYMOND J. POOL, of the University of Nebraska, has been granted a leave of absence from May 15, in order that he may continue his studies of the vegetation of the Sand Hills of Nebraska. It is planned to extend the detailed work of last summer over a wide territory and into portions of the hills that have never been visited by botanists. Special attention will be paid to the bunchgrass association, to the preparation of vegetation maps and to the vegetation (exclusive of the algæ) of the alkaline lakes which are scattered in great numbers throughout the region. A collection of herbarium specimens will also be made. Professor Pool will be assisted by Mr. Donald Folsom, who is at present the collector for the department of botany in the university.

DR. DAVID T. DAY, of the U. S. Geological Survey, has gone to Vienna, Austria, to attend the meeting of the International Commission of Petroleum Testing Methods.

PROFESSOR A. A. MICHELSON, of the University of Chicago, will give the annual address before the Michigan Academy of Science at Ann Arbor on March 27. His lecture will be on "Iridescent Colors of Birds and Insects."

PROFESSOR H. S. JENNINGS, of the Johns Hopkins University, gave the tenth Hervey lecture at the New York Academy of Medicine on March 2, his subject being "Old Age, Death and the Meaning of Conjugation in Lower Animals."

AT the meeting of the Chemical Society at George Washington University on February 15, Dr. Frank Wigglesworth Clark, chief chemist of the U. S. Geological Survey and

professor of mineralogical chemistry at the university, gave an address on the "Composition of the Earth's Crust."

DR. L. A. BAUER, director of the Department of Terrestrial Magnetism of the Carnegie Institution, gave an address on "The Recent Cruise of the Non-magnetic Ship *Carnegie*" at the College of the City of New York on March 1.

THE following lectures have recently been delivered at the University of Missouri under the auspices of the Scientific Association: Professor W. Johannsen, of the University of Copenhagen, February 21 and 22, on "Modern Problems of Heredity"; Professor Albert Bushnell Hart, of Harvard University, February 24, on "America in the Orient."

A LECTURE on sanitation and public health, under the auspices of the department of sanitary engineering of the University of Pittsburgh, was given in Thaw Hall, on March 5, by Professor C.-E. A. Winslow, of the College of the City of New York. This was the third in this series of lectures, the others having been given by Professor Wm. T. Sedgwick and Dr. M. J. Rosenau, respectively. Professor Winslow discussed "Air Supply and the Public Health."

PROFESSOR GEORGE GRANT MACCURDY gave a public lecture in the University Chapel, Columbus, on the evening of March 1 by invitation of the Omega Chapter of the Sigma Xi of the Ohio State University, his subject being "Pre-Columbia Art."

PROFESSOR J. HOWARD MATHEWS, of the department of chemistry of the University of Wisconsin, gave an illustrated lecture on February 7 before the Purdue Chapter of Sigma Xi, at Lafayette, Indiana, on "The Scientific Applications of Color Photography."

UNDER the auspices of the department of geology, Professor Ellsworth Huntington, of Yale University, delivered three illustrated lectures on the general subject of "The Desert" at the University of Michigan, on February 28 and 29 and on March 1. The subjects of his lectures were: "Chinese Turkestan as an Example of the Relation of Deserts

to Geological Processes," "Palestine as an Example of the Effect of Minute Differences of Geological Structure upon History" and "Historic Changes of Climate as an Example of the Application of Geological Methods to Historical Problems."

DR. C. L. BABCOCK, of Boston, lectured under the auspices of the department of archeology at Oberlin College on March 5 on the excavations at Cnossus in Crete. Dr. Babcock studied the excavating done by Mr. Arthur Evans, the result of which was the discovery of what is very probably the palace of King Minos, so complicated in detail that it may well have been called the labyrinth. These discoveries have moved back the beginnings of European history well toward 10,000 B.C. The lecture was illustrated with a large number of stereopticon slides prepared by Dr. Babcock himself supplemented by others loaned from the Boston Museum of Fine Arts.

It is proposed to erect a monument to Dr. J. Janssen, eminent for his work in astrophysics. The officers of the organizing committee are: *President*, H. Poincaré; *vice-presidents*, B. Baillaud and G. Bigourdan; *secretary*, P. Puiseux; *treasurer*, H. Dehérain, Bibliothèque à l'Institut, Paris, to whom contributions should be sent.

MR. GEORGE MAW, known for his important contributions to botany and other natural sciences, died at Kenley, Surrey, on February 7, aged eighty years.

THE death is announced at Bergen of Dr. G. H. A. Hansen, eminent for the discovery of the bacillus of leprosy in 1871.

M. EUGÈNE CAVENTON, the distinguished chemist and member of the French Academy of Medicine since 1870, has died at the age of eighty-three years.

THE committee on scientific research of the American Medical Association has charge of a small fund which is to be used to promote research. The committee is desirous that this money should be used to meet actual needs and to promote investigative work not otherwise adequately provided for. Applications

for grants are invited. The applicant should state fully the purpose for which the grant is desired; the qualifications of the applicant and the general opportunities and conditions under which the work is to be done. The members of the committee are Ludvig Hektoen, Chicago (1743 W. Harrison St.), Graham Lusk, New York, and Eugene L. Opie, St. Louis, Mo.

MR. GEORGE HENRY VERRALL, formerly Conservative M.P. for East Cambridgeshire, a former president of the Royal Entomological Society, who died on September 16, left his collection of British Diptera and the cabinets in which it is contained to his nephew, James Edward Collin, conditioned upon his offering to the Natural History Museum, South Kensington, three pairs of each species of which he possessed a full series (six pairs constitute a full series), and at least one pair of each species of which he possessed more than one pair; and all his real and personal estate in the parish of Wicken, Cambs, to the National Trust for places of historic interest or natural beauty.

THE Biological Survey of the Agricultural Department has secured the cooperation of the National Zoological Park in experiments in breeding mink for the purpose of ascertaining the possibilities of rearing them in captivity for commercial purposes.

UNIVERSITY AND EDUCATIONAL NEWS

GIFTS of over half a million dollars to the University of California have just been consummated, through the deeding of property by trustees for the late Mrs. Jane K. Sather, of Oakland. Plans have been begun for the Sather Campanile, a lofty bell-tower, for which Mrs. Sather provided some \$200,000. Two professorships are endowed; the Jane K. Sather chairs in classical literature and history will each have an endowment of approximately \$120,000. Endowment is provided for three book funds.

OFFICIAL record has been made in the city of Philadelphia of the transfer of the new tuberculosis hospital built and endowed by Mr. Henry Phipps to the University of Penn-

sylvania. The cost of the new building is \$300,000, and the entire project will represent an outlay of about \$1,000,000.

THE Illinois State Supreme Court has rendered a decision which declares unconstitutional an act of the last legislature which voted an item of \$60,000 for the medical school of the university. As many of the other acts of the legislature were passed in the same manner, there is considerable confusion in the minds of people as to what the outcome may be. It is thought that a special session of the legislature may be called to straighten out affairs.

THE departments of horticulture and plant pathology of the University of Wisconsin have moved into their new building. It is a two-story and basement brick structure, 48 by 128 feet, and with attic space for laboratories. The cost of the building was \$60,000, exclusive of the four greenhouses, potting house and pathologium, situated in the rear of the building. In the basement of the new structure are spray laboratories, fruit rooms and bulb rooms, while the offices, lecture rooms and general laboratories of the horticulture department are on the first floor. The second floor is given over to the plant pathology department, under Professor L. R. Jones. Professor J. G. Moore is at the head of the horticulture department.

THE royal commission on university education in London has recommended a building for the university to be placed on a vacant site of more than 100,000 square feet immediately behind the extension of the British Museum. The site consists of four plots, two on each side of the new British Museum Avenue, on one of which it is proposed that a spacious hall should be built for the university, the other three plots being used for administration, library, small lecture theaters and rooms for graduates. The site is part of the Bedford estate, and it is stated that the Duke of Bedford is prepared to dispose of it for the purposes suggested.

DR. ARTHUR HOLMES, assistant professor of psychology at the University of Pennsylvania,

has accepted the post of dean of the faculties of Pennsylvania State College.

THE following appointments have been announced for the medical department of the University of Pennsylvania: Dr. Edward Lodholz is to be assistant professor of physiology; Dr. W. N. F. Addison, assistant professor of normal histology; Dr. George H. Fetterolf, assistant professor of anatomy; Dr. L. A. Ryan, assistant professor of chemistry and toxicology.

DR. E. T. WHITTAKER, F.R.S., royal astronomer of Ireland, has been appointed professor of mathematics in the University of Edinburgh, in succession to the late Professor Chrystal.

DISCUSSION AND CORRESPONDENCE

REPLY TO HOLMES'S CRITICISM OF "LIGHT AND THE BEHAVIOR OF ORGANISMS"

In a review of the book entitled "Light and the Behavior of Organisms," which appeared in this Journal, June 23, 1911 (pp. 964-966), the author raised several points that call for elucidation. Before entering upon the discussion of these points, however, I wish to take this opportunity to state my regret in having overlooked the work of several investigators bearing on some of the subjects treated, especially that of R. S. Lillie on the reactions of *Arenicola* larvæ, to which Holmes calls attention.

After referring to the numerous attacks made in the book in question, on Loeb's theories of orientation, Holmes says (p. 964):

Mass's own investigations seem to afford about as good support as has been furnished for the theory which he so persistently attacks.

He then gives two cases in support of his contention:

1. No clearer case of orientation through the local response of the part directly stimulated could well be imagined than the one afforded by *Amæba*, and the author admits that the "method of orientation is in harmony with much in Verworn's theory and also with the essentials in Loeb's." But he adds that "it does not, however, support the idea connected with these theories, that a constant intensity produces a constant directive stimula-

tion." I am not sure that I understand the pertinency of the criticism, for there is nothing in the theories of either of these writers which implies that the actual stimulating effect of any directive agency is subject to no variation.

2. Referring to orientation of *Arenicola* larvæ he says (p. 965):

Orientation in this form is apparently as automatically regulated an activity as one might expect according to the well-known theory of Loeb.

The point at issue here clearly concerns the question as to whether the methods of orientation in *Amæba* and *Arenicola*, as described in my book, are in accord with Loeb's theories of orientation. To settle this question it is of course necessary first of all to understand these theories. I say theories, for, contrary to my critic's assumption, there are three instead of one, as pointed out in my book, pp. 23-35, especially in the summary (p. 54) where the following statement is found:

In 1888 Loeb held that orientation in animals is controlled by the direction in which the rays of light pass through the tissue. From 1889 to 1903 he advocated the idea that orientation is controlled by the direction in which the rays strike the surface, or the angle they make with the surface. His statements from 1906 to 1909 indicate that he thinks that orientation is regulated by the relative intensity of light on symmetrically located sensitive structures on opposite sides of the organism.

The idea that orientation is the result of continuous action of light is common to all of these theories and is undoubtedly their most important distinguishing characteristic. Loeb has repeatedly stated this in unmistakable terms. Witness, e. g., the following statement found in "Dynamics of Living Matter" (p. 135): Heliotropism is "a function of the constant intensity," and the same idea expressed more fully in the same publication on pp. 117-119, 130-131, 138-139. My critic has evidently failed to grasp this idea in spite of the fact that I have repeatedly stated it in different forms in quotations from the references just given and others, indeed even to such an extent that one of my reviewers objects to the repetition as superfluous.

In order to show that an organism orients in accord with Loeb's theories it is conse-

quently necessary to prove that the response is due to "constant intensity," i. e., that the orienting stimulus acts continuously and is not due to changes of intensity. This I have been unable to do in any case whatsoever in spite of persistent efforts, and as far as I am aware it has never been done. It was owing to this that I made the statement that the orienting reactions in *Amœba* do not support the idea connected with the theories of Loeb and Verworn that "a constant intensity produces a constant directive stimulation" quoted by Holmes. His failure to "understand the pertinency of this criticism," as he says, indicates that he did not understand these theories.

The second case which Holmes cites in support of his contention that my investigations lend support to Loeb's theories shows even more clearly than the first that he did not understand these theories. After admitting that in case of the orientation in *Arenicola* larvæ "the question remains open whether the stimulus is produced by the direct action of light on the sensitive surface of the animal or by changes in intensity of the stimulus caused by the lateral movements of the body" he maintains that orientation in these animals is in accord with "the well-known theory of Loeb" because it is "*apparently automatically . . . regulated*" (italics mine). Thus admitting that it can not be proved that orientation is due to continuous stimulation, he would make automaticity the criterion of Loeb's theories, ignoring all other distinguishing characteristics found in them.

It is true that Loeb often uses the term automatic in discussing reactions which he calls tropisms, but what does it mean? Automatic means mechanically self-acting, that is, involuntary. In accord with this definition are there any reactions whatsoever in *Arenicola* or in any other organism below man which are not automatic? Investigations and speculations without end have been directed toward the solution of this very problem and yet there are few bold enough to say that it has been solved for even a single case. Of what possible value then can automaticity be

as a distinguishing characteristic of a group of reactions supposed to be specific, and what bearing can the statement that the orienting reactions of *Arenicola* larvæ are *apparently automatic* have on the mechanics of orientation (tropisms) of this or any other organisms?

It is precisely such loose and uncritical statements as Holmes has made regarding Loeb's theories with the suggestion of such impossible criteria as automaticity that have brought the discussion centering around the term "tropism" to the chaotic condition in which it is found at present. To show that a reaction is in accord with any one of Loeb's three theories it must of course be demonstrated that it is in harmony with all of its characteristics, not merely with one of them, as my critic seems to imply. It must be proved, among other things, as demonstrated above, that the external stimulating agent acts continuously in the process of orientation. Until this is done Loeb's statement that orientation is a function of the constant intensity must be classified as anthropomorphic speculation. And if the statement of my critic is true, that my investigations afford about as good support as has been furnished for Loeb's theories, it is evident that they rest on extremely nebulous foundations. If Holmes can produce a single case in which he can prove that orientation occurs in accord with any of these theories I trust that he will do so in answer to my reply to his criticism.

My discussion concerning certain theoretical views held by Jennings brings out the most caustic criticism that Holmes has to offer. He quotes the following paragraph from my book:

Every step in the development of the theory [Jennings] is supported by numerous experimental facts and all seems to fit what is known concerning the reactions of organisms. Reactions, according to this theory, are, as stated above, primarily due to physiological states. External agents ordinarily produce reactions through the effect they have on these states. By the application of this idea all the different phenomena connected with reactions to light as summarized at the beginning of this chapter can be accounted for.

This quotation is followed by a paragraph containing the following sarcastic remarks (p. 966):

It would indeed be comforting to be able to repose with such a spirit of confidence and contentment in a general philosophy of behavior, but it is perhaps pertinent to enquire if the author has not been deceived with the delusive appearance of explanation where no real explanation has been given. . . . Phenomena may thus be "accounted for" on the basis of varying internal states, but as it is admitted that in most cases we are entirely ignorant of what these states are we are about as much enlightened as we are by the celebrated explanation of the sleep-producing effect of opium by attributing it to a dormitive principle.

If I had said nothing more than is contained in the paragraph which Holmes quoted from my book there might be some excuse for such criticism, but the very sentence following this paragraph reads:

But what are these physiological states and of what do they consist? That there are such states in organisms can not reasonably be doubted, and that the reactions are dependent upon them much as Jennings assumes, seems to me to have been well established in his work. But what regulates the physiological states is a question concerning which we have as yet but little knowledge.

The two pages in my book following this quotation are devoted to an attempt to illustrate the limitation of Jennings's ideas, and it is concluded (p. 375):

For all that is known to the contrary, subjective factors, entelechies, or psychoids, factors foreign to inorganics, may have a hand in controlling physiological changes and consequently the reactions. Such factors have been postulated by the vitalists and neovitalists, notably by Hans Driesch.

I am at a loss to know how my critic could have read even superficially these statements and the argument connected with them and still conclude that I had been deceived with the delusive appearance of explanation where no real explanation has been given. I am not certain what Holmes means by a real explanation, but I am certain that neither Jennings nor I have ever even so much as intimated that the demonstration that reactions

of organisms are dependent in a definite way upon internal states constitutes a complete explanation of behavior. In the paragraph which Holmes singled out for attack with reference to this question I did not even use the term explanation, merely stating that the reactions could be "accounted for" by the application of certain ideas regarding internal states. Thus it is evident that his caustic criticism is directed not toward anything actually stated, but toward an imaginary implication.

However, to intimate as Holmes does in the second quotation given above, that a demonstration of the actual value of internal factors in behavior is useless because it is not known precisely what the internal factors are, is expressing a principle which if applied generally would at once do away with scientific investigation, for is it not well known that science in all of its aspects rests upon phenomena which are clothed in mystery? A scientific explanation, as I see it, consists of a demonstration of the order of events involved in the phenomenon. The demonstration that in the observed phenomena known as behavior events within the organism occur in a certain order in the whole series of events ending in these phenomena (behavior) is as truly an explanation as any we have in science. It is one step in the series, even if only a small one, which, as far as can be predicted at present, leads back into the unknown without end.

I can understand the statements of Holmes in his criticisms only on the assumption that he reviewed my book hurriedly and carelessly. As evidence of this we have not only his erroneous conceptions regarding Loeb's definition of tropism and his failure to grasp my ideas in the discussion of the theoretical views of Jennings, but also the fact that in his short quotation from my book there are three changes from the original. Moreover, his statement (p. 965) that I have presented "no discussion of any theoretical attempt to explain the reversal of phototaxis" is not true, as reference to page 370 will show.

S. O. MAST

JOHNS HOPKINS UNIVERSITY

SCIENTIFIC BOOKS

Commercial Geography. By ALBERT PERRY BRIGHAM. Boston, Ginn & Co. 1911. 28 chapters, 449 pages, 17 colored maps and 253 illustrations. \$1.30.

This latest addition to the texts of commercial geography will very rapidly prove its worth because of the practical pedagogic principles followed in the arrangement and presentation of the material.

The great raw materials of world-wide interest and of vast significance in the commercial world are concretely presented, as Part I., in a series of chapters on wheat, cotton, cattle, iron and coal. A study of the activities centered about each of these great raw materials gives the student a broad outlook and furnishes a basis for Chapter VI. on the Principles of Commercial Geography. The discussion of raw materials before the considerations of the geographic principles will be welcomed by educators as far superior to the usual broad generalizations concerning a conglomerate hodgepodge of land forms, climate, rivers, lakes, raw materials, transportations and industry. Chapter IV. on Iron is typical of the method in which this text presents all of the five great raw materials. This chapter has excellent views, diagrams, maps and graphs.

The five types of raw materials are followed by the discussion and application of the principles to the United States which forms Part II. of the text. This presents in eleven chapters the physical features; plant, animal and mineral industries; water resources; transportation; commerce; centers of general industry and the concentration of industries. The space given to the United States is more than the average text, but this added emphasis is in accord with the general movement among educators to require from students a better understanding of our own country. The maps of production are especially clear and are constructed so that a comparison of various states and regions is very easy. The water resources of the United States is a chapter not generally considered in a commercial geography, but it

makes a most valuable addition. The concentration of industries and the centers of general industry is another innovation which is most heartily endorsed by instructors as excellent material well designed for instruction in modern commercial geography.

The foreign countries receive a brief but ample discussion for high school students. In each of the countries the proper emphasis is given the predominant industry of each individual country. The final chapter on World Commerce is an excellent application of the geographic principles which have been developed in the previous sections of the text.

In the writer's opinion this text has many points of superiority which greatly strengthen the instruction in commercial geography.

*SOME EARLY PHYSIOGRAPHIC
INFERENCES*

THE inferences of early travelers as to the physiography of a region are always interesting if the traveler is a good observer. The following references may not be new to some geologists, but they were new to the writer and seem worth publishing.

Wm. Darby in his "Emigrant's Guide," 1811, states that one of the branches of the St. Francois River "appears to have been an ancient outlet of the Mississippi" (page 139). Apropos of the same region, James Hall in his "Notes on the Western States," Philadelphia, 1838, says "About midway between St. Louis and the mouth of the Ohio, masses of limestone rock are seen on either side, which, though now unconnected, have the appearance of once having formed a continuous ridge crossing the river in an oblique direction" (page 47). Both these travelers, in looking across the southeast lowlands of Missouri, inferred general truths that, taken together, would form important links in the history so admirably worked out nearly a century later by Professor C. F. Marbut.¹

¹"The Evolution of the Northern Part of the

As Darby infers, the Mississippi formerly flowed west of its present channel. It was separated from the Ohio by an interfluvium, the remnants of which are the "continuous ridge" mentioned by Hall. By two successive captures the Ohio diverted the Mississippi; the final capture led the Mississippi through its present gorge where the "masses of limestone rock are seen on either side."

Henri Peyroux de la Condreniere, commandant at Ste. Genevieve from 1787 to 1796, was a man of considerable scientific ability. In one of his essays he maintains that the Great Lakes formerly discharged into the Mississippi by way of the Illinois River. He reasons that the valley is too wide and deep to have been eroded by the present Illinois River. Another reason quoted is not so well founded; the "vast alluvium" stretching along the Mississippi to the Gulf is also held to indicate a drainage from the Great Lakes. This conjecture is an interesting prelude to the work which has shown the extent and drainage of those great marginal glacial lakes that preceded the present Great Lakes. The quotation has been handed down by Brackenridge, the lawyer-traveler in his "Recollections of the West," second edition, Philadelphia, 1868 (page 241). He (Brackenridge) adds prophetically "At no distant day the labor and ingenuity of man will restore the connection between the Lakes and the Mississippi by means of an artificial channel."

SPECIAL ARTICLES

HORNS IN SHEEP AS A TYPICAL SEX-LIMITED CHARACTER¹

SEVERAL years ago Wood (1905) published a note in which he showed that, in a cross between a Dorset Horn and a Suffolk (belonging to Lowlands of Southeast Missouri," University of Missouri Studies, Vol. I., No. 3, 1902.

¹Joint contribution from the New Hampshire Agricultural Experiment Station and the Station for Experimental Evolution, Carnegie Institution of Washington.

ing to a hornless breed of sheep), the male offspring all developed horns but the female offspring remained hornless. He showed further that in the F₂ generation hornless males arise, and these do not carry the determiner for horns, and horned females, but only when they have the determiner duplex. Bateson (1909, p. 173) has discussed these facts and drawn the conclusion: "Sex itself acts as a specific interference, stopping or inhibiting the effects of a dominant factor, and it is not a little remarkable that the inhibition occurs always, so far as we know, in the female, never in the male." He admits, however, the difficulty in distinguishing between this probability and the other possibility; viz., that the male provides a stimulating factor. Castle (1911, p. 102) concludes that the reason horns are more strongly developed in males than females is "the presence of the male sex-gland in the body, or rather probably some substance given off into the blood from the sex gland, favoring growth of the horns"; and he adds that if the male Merino sheep (in which, usually, the male, and the male only is horned) is castrated early in life no horns are formed. He gives no reference for the last statement; and in view of the variability of the horned condition in the males of the "Merinos" the conditions of the experiments would have to be carefully considered before such a result could be accepted as settling the question of the dependence of horns in heterozygous males upon a secretion from the testis.

The hypothesis that we have adopted and which works with entire satisfaction assumes, first, that, as in man so in sheep, the male is heterozygous (simplex) in sex. One sex-chromosome is then to be expected in the male, and substantially this condition has been found to hold for man by Guyer (1910). The female will then be duplex in respect to sex. One further assumption is necessary; there is an inhibitor to horn formation, and this is located on the sex chromosome; consequently it is simplex in the male and duplex in the female. Thus it belongs to the well-known class of sex-limited characters. The inhibi-

tor, then (designated in the table by the letter I , its absence by i), will always be double in the female and single in the male and, in the gametes, will always be associated with the sex-chromosome, which is designated throughout by the symbol X ; its absence by x . In the zygote the single inhibitor is incapable of preventing the development of the determiner

for the horn (II) even when the latter is only simplex. But the double inhibitor is capable of preventing the single horn (Hh) determiner, but not the double determiner (HH).

The table gives a summary of matings used, their hypothetical somatic and gametic composition, and the proportion of each sort of zygote that will be formed in each sex.

The actual frequency of offspring derived from each mating is given on the left of the table; the expected proportions in the more complex cases being given above the actual findings in parenthesis. The matings were made and the offspring examined in major part at the New Hampshire Agricultural Experiment Station and in minor part at the Station for Experimental Evolution. The latter station was able to contribute especially to the results of later generations. For horned females, Dorsets were used; for horned males Rambouillets, Dorsets and the Scottish 4-horned race. As hornless races the Downs were chiefly employed. It is not our purpose now to give complete details, as the experiments are being continued and full data will be deferred until the publication of our final report.

The results of the table accord very closely with expectation, so that we are justified in concluding that an explanation of the results like that we offer is the correct one. By our formula, then, the case of inheritance of horns in sheep is brought quite into line with that of other sex-limited characters, its peculiarities being due to an inhibitor of horn development that is carried in the sex-chromosome.

THE "STOMACH STONES" OF REPTILES

GASTROLITHS have been known to occur, mingled with the remains of extinct reptiles,

for many years and much attention has been called to them in the pages of SCIENCE and elsewhere, especially by Mudge, Seeley, Williston, Eastman, Wieland and Brown. Interesting parallels have been cited among several living vertebrates. There has been some contention that the stones were taken for the purpose of a "gastric mill," but they were in part at least accidental. There seems to be some evidence for the conclusion that the plesiosaurs, at least, selected stones for this purpose, though this may have been more accidental than we think. Recently there has been brought to my attention by Mr. Edward Taylor, of the University of Kansas, an interesting case of stone swallowing by a lizard, *Phrynosoma cornutum* Harlan. Only a single specimen is at hand for the data, but it is of sufficient interest in connection with identical habits among fossil reptiles to be recorded. The horned "toad" in question is a very large adult female collected by the late Dr. F. H. Snow in the Magdalen Mountains of New Mexico. In the stomach were twenty large, somewhat abraded stones of a rock which resembled lava. Some of the stones are very large, for the size of the animal, measuring nearly a third of an inch in diameter. There were also in the stomach about 200 of the large red ants, of an undetermined species, which make the large mounds so common to the western traveler. The animal had undoubtedly picked up the stones with the ants from the top of the mound and the association is probably accidental. That they served the purpose of a "gastric mill" once inside the digestive canal can not be doubted, whether the animal willed or no.

In this connection it may be of interest to the readers of these pages to call attention to some large Cretaceous sharks which have, within the past few months, been received at the University of Kansas Museum. In one specimen, consisting almost entirely of scattered vertebral cartilages, there are associated many hundreds of greatly abraded, very smooth and polished stones of white and black quartzite. That they belong with the shark can not be doubted on account of the

association. The pebbles resemble to a great extent those figured by Dr. Williston some years ago as occurring with a pleisosaur. Another, nearly complete skeleton of a large shark, *Isurus mantelli* Ag., has preserved the larger part of the cranial cartilages. The sharks will shortly be described in detail and further reference need not be made to them here.

THE WASHINGTON MEETING OF THE
AMERICAN CHEMICAL SOCIETY¹

The meetings of the society were held from Wednesday, December 27, to Saturday, December 30.

On Wednesday morning four papers were presented in joint session of the Section of Chemical Education and the Division of Physical and Inorganic Chemistry:

A. A. NOYES (chairman): *The Teaching of Physical Chemistry*.

W. D. BANCROFT: *Physical Chemistry in the Introductory Course*.

In the introductory course we should include: gas law; boiling-point curve; solubility; a brief statement of the dissociation theory; qualitative mass law, and qualitative catalysis. We should exclude: quantitative mass law; dilution law; solubility product, and reaction velocity. I am doubtful about electrolysis and osmotic pressure; but I should include the former and exclude the latter.

H. C. JONES: *The Introduction of Physical Chemical Conceptions in the Early Stages of the Teaching of General Chemistry*.

J. HOWARD MATHEWS: *Some Applications of Color Photography in the Teaching of Physical Chemistry*. (Illustrated.)

The theory and manipulations of the "screen-plate" processes of color photography were described briefly. Numerous scientific applications of color photography were pointed out, and each application was illustrated by color photographs thrown on the screen. The process has been found to be exceedingly useful in photographing inter-

ference figures and in recording the interference colors observed when certain crystals are viewed in polarized light. In many of the slides illustrating the latter, selenite plates were used to produce backgrounds of strong contrast and brilliant color. Photographs of "thin-sections" of various rocks showing their characteristic appearance in polarized light were also shown. The process has been found to be particularly well adapted to the projection of spectrum charts, etc., in colors. The absorption bands of chlorophyll were photographed directly in the spectroscope and a fairly accurate record obtained. Pure spectrum colors are not truly rendered by the process, since the color is always dependent on the dyes used to color the starch grains. However, an attempt to photograph the fluorescence of solutions of fluorescein met with considerable success.

The following three papers were presented in general meeting on Wednesday afternoon:

PRESIDENT FRANKFORTER (Section C): *The Resins and their Chemical Relations to the Terpenes*.

To be published in SCIENCE.

H. P. TALBOT (chairman Division of Physical and Inorganic Chemistry): *Privileges and Responsibilities of the Chemical Analyst*.

A. L. VOGEL: *Ostwald's Proposed International Institute of Chemistry (chiefly bibliography and library practise)*.

On Thursday evening two addresses were given in general session:

ALEXANDER SMITH (president American Chemical Society): *An Early Physical Chemist*.

Published in the issue of SCIENCE for February 1.
FRANK B. KENDRICK and H. E. HOWE: *Lantern Experiments on Reactions in Heterogeneous Systems*.

A series of lantern illustrations of the effect of temperature, pressure, concentration, surface, osmotic pressure, etc., on reactions in heterogeneous systems. Several adaptations of a Bausch and Lomb balopticon were described, including a modification of the Töpler "Schlieren" apparatus for projection and the use of the lantern as a photographic camera.

On Friday a symposium on Mineral Waters was held before the Division of Industrial Chemists and Chemical Engineers. Titles of papers presented before this important symposium were published in SCIENCE of January 12. The papers themselves together with the voluminous discussion will be featured in the March issue of the *Journal of Industrial and Engineering Chemistry*.

¹Most of these papers will be published in the *Journal of the American Chemical Society* or in the *Journal of Industrial and Engineering Chemistry*.

The following papers were presented before the various divisional meetings:

DIVISION OF AGRICULTURAL AND FOOD CHEMISTRY

H. E. Barnard, *chairman*.

B. E. Curry, *secretary*.

H. E. BARNARD (chairman's address): *A Study of the Pollution of the Ohio River Bordering Indiana*.

During the summer of 1911, the Indiana State Board of Health made a comprehensive study of the condition of the Ohio River bordering Indiana. A chemical and bacterial laboratory was fitted up in a house boat in which samples taken each mile were analyzed. The chemical analysis included the estimation of nitrates, the estimation of nitrites, the estimation of chlorine, of oxygen consumed, the estimation of dissolved oxygen, the estimation of alkalinity and turbidity. The bacterial analyses: an estimation of the number of bacteria; the presumptive test for *B. Coli* and the differential test for *B. Coli* on every tenth sample.

The work, which extended over three months, established new data on the purification of flowing streams and is a valuable contribution to the knowledge of the character of the Ohio River. The report will not be completed for publication until the spring of 1912.

W. A. WITHERS and F. W. SHERWOOD: *A Modification of the Tiemann-Schulze Method*.

B. L. MURRAY: *Determination of Small Amounts of Caffeine—A Comparison of Methods*.

The author has compared the results obtained by the method of Görter and by that of Lendrich and Nottbohm, using coffee and coffee preparations as samples. It is shown that when only small amounts of caffeine, particularly when less than 0.5 per cent., are present the Görter method yields results 50 to 100 per cent. higher than those of the Lendrich and Nottbohm. The author believes the Lendrich and Nottbohm method preferable. About fifty analyses are tabulated, each with duplicate results.

W. H. ROSS and RAYMOND C. BENNER: *The Filtration of Soil Solutions. A New Filter for This and Similar Purposes*.

FERNAND BRUNSCHWIG: *The Presence of Lead and Copper in Cream of Tartar and Tartaric Acid. Technical Methods to Purify these Products*.

J. B. BATHER: *The Forms of Phosphorus in Cotton-seed Meal*.

J. F. SNELL: *An Electrical Conductivity Test for Purity of Maple Syrup*.

The syrup is diluted with two volumes of water and the electrical conductivity measured at 25° C., with a Wheatstone bridge and telephone in the customary manner. The specific conductivity multiplied by 100,000 gives the "conductivity value." The test is simple and rapid.

Among 57 samples of genuine syrups from Quebec, Ontario and Vermont, only two samples (these two not market syrups) give conductivity values over 200. The minimum value found was 110, the syrup giving this being the one prepared under the supervision of the Vermont Agricultural Experiment Station, under such conditions as to give the malate of lime every opportunity to settle out. Values less than 120 were given by only 3 samples—all very light colored, high-quality goods. Genuine syrups may, therefore, be expected to give values between 100 and 200—Canadian syrups ordinarily between 120 and 200.

Syrups compounded of maple syrup with over 50 per cent. of its weight of an equally dense syrup made from granulated cane sugar give values below 100. Imitation syrups made from granulated sugar and artificial maple flavors give still lower values. Such gross adulterations with refined cane sugar are immediately indicated by this test.

JOHN STEWART: *A Brief Study of the Phosphorus Associated with the Matière Noire*.

This paper attempts to answer the question: Is the phosphorus in the *Matière Noire* organic or inorganic? Treatment of the soil with NH_4OH fails to extract any phosphorus. Partial removal of acid soluble phosphorus and complete removal of acid soluble phosphorus, followed in each case with NH_4OH extraction, gives ammoniacal solutions with practically identical phosphorus content; viz., approximately 0.0103 per cent. on soil. The conclusion is that all the phosphorus associated with the *Matière Noire* is organically combined. Practically all the iron and aluminum present in the *Matière Noire* are organic. Hydrolysis takes place during extraction with alkali and a large part of the phosphorus and some iron and aluminum are converted into inorganic forms.

Several precipitating reagents for separating inorganic phosphorus from organic were tried; but results were unsatisfactory.

EMMA CRANDAL: *The Composition of Free Oyster Liquid*.

Present data on the composition of the oyster is meager. The author has endeavored, by a

study of oysters and oyster liquor purchased in the open market, to establish factors which will be helpful in showing whether or not oysters have been floated or watered in transit. This she does by a study of the total solids, ash nitrogen, chlorine of both the free liquor and oyster meats and calcium content, immersion refractometer reading. The data obtained are not conclusive and further work is proposed in the hope that it may be possible to establish definite factors of composition.

H. E. BISHOP: *New Data on the Composition of Prepared Mustards.*

Prepared mustard is a paste composed of ground mustard seed with salt, spices and vinegar and should conform to certain standards of composition. The author, in the course of a study of prepared mustards, finds that they vary greatly in character. He has endeavored by determining certain factors, namely, total solids, ash, sodium chloride, acidity, starch, crude fiber, protein, etc., to gather data of value in determining whether prepared mustards are pure or adulterated. The author finds a great variation in composition. The data at hand are as yet inconclusive. Further work is proposed in the hope that new data, throwing additional light on the composition of mustards, will be forthcoming.

J. M. PRICE: *A Method for the Separation of the Seven Coal-tar Colors when Occurring in Mixtures.*

L. H. SMITH: *Altering the Composition of Indian Corn by Seed Selection.*

In 1896 the Illinois Agricultural Experiment Station began experiments with a variety of corn to alter the chemical composition of the corn by seed selection. Fourteen years of breeding have produced the following results: The protein content has been increased from 10.92 per cent. in the original, to 14.87 per cent. in the crop of 1910. At the same time by selecting in the opposite direction, the protein has been decreased to 8.25 per cent.

Even more striking changes have been produced in the oil content. In the original corn the percentage of oil was 4.70. After fourteen years selection for high oil a strain has been produced which carried 7.72 per cent., while the corresponding selection for low oil has resulted in a strain which contains 2.11 per cent.

J. F. BREAZEALE and J. A. LEClerc: *Influence of Reaction of Culture Medium on Root Development of Wheat Seedlings.*

J. A. LEClerc and B. R. JACOBS: *The study of True and Imitation Graham Flour.*

C. C. MOORE: *The Desiccation of Potatoes and the Uses of the Product.*

The desiccation of potatoes has been commercially developed in Germany, but the product has not been suitable for the manufacture of starch. Investigations have shown that a dried potato product can be prepared in a way suitable for starch manufacture. Owing to the greater degree of fineness to which the dried product can be reduced, over 90 per cent. of the starch can be separated in the usual washing and decantation methods, as against a recovery of 65 to 75 per cent. of starch when potatoes are ground in a fresh state.

P. A. YODER: *Marking of Porcelain and Silica Crucibles, etc.*

Consecutive numbers in platinum or china colors may conveniently and neatly be put upon porcelain or silica crucibles, etc., by use of rubber type.

To apply china colors, a sizing like "Fat Oil," is first stamped upon the crucible, the dry pigment then dusted on, and after the varnish has set, the excess brushed off and the crucible fired in a muffle at a red heat for an hour. Blacks, especially "Lettering Black," gave very satisfactory results and the numbers resisted treatment with hot nitric acid and alkali solutions.

CHARLES FOX: *Perilla Oil.*

P. E. BROWN and R. E. SMITH: *Bacterial Activities in Frozen Soils.*

It was found, in the course of an experiment conducted during the winter months of 1910-11, that bacteria which developed on synthetic agar plates, ammonifying, nitrifying, denitrifying and nitrogen-fixing species whose activities were tested by the beaker method, were alive and multiplied in frozen soils.

In explanation of this, the theory is advanced that when soils freeze the hygroscopic water remains uncoagulated, because of the surface tension exerted by the soil particles on the film water, its normal concentration in salts, and its increased concentration occurring when the main body of soil water begins to freeze.

Temperature exerted more influence than moisture on the bacteria developing on the agar plates.

H. H. HANSON: *Report of Progress in a Study of the Maine Sardine Industry.*

This paper gives an account of the industry from the taking of the fish to the finished product in the can, mentions problems of economic interest to the packers and others of scientific importance. There are three important respects in which the Maine sardines differ from the foreign sardines, of which the French pack is recognized as the most desirable. First, the fish packed in France under the name sardine is the *Clupea pilchardus*, while the fish packed in Maine under that name is the *Clupea harengus*, two distinct species of the same family. Second, French sardines are packed in olive oil while the Maine sardines are put up in cotton-seed oil. Third, in handling the French pack the single fish is the unit and quality is at all times considered of paramount importance; while in handling the Maine pack the hog-head is the unit and quantity is always sought. The French sardine retails for from thirty-five to sixty cents per can, while the Maine sardine retails for the most part for five cents. The markets for these two grades seem to be well established.

Indications seem to point to the conclusion that swelled cans are caused for the most part by imperfect sealing, although in some cases it would seem as though the sterilizing process was not sufficient.

An important food of the sardines, known to the trade as "red feed" seems to cause rapid deterioration of the fish. This has been identified as a microscopic crustacean of the family Centropagidae, called *Temora longicornis*. It has been suggested that auto-digestion induced by an enzyme peculiar to this crustacean may be responsible for the rapid deterioration, but it seems more likely from present knowledge of the subject that a methylamine is the cause. Investigation is still going on.

W. B. SMITH: *The Index of Refraction of the Mixed Acids of Fatty Oils.*

Determinations of the ratio between the refraction of oils and of their insoluble acids gave, for linseed, cod liver, soy bean, corn, rapeseed, cottonseed, peanut and olive oils, values between 0.9933 and 0.9942; and for lard, lard stearin, oleo oil, oleo stearin, cocoa butter, butter, palmit oil, coconut oil and a mixture of cottonseed oil and oleo stearin, 0.9923 to 0.9941.

These figures are shown to be in accord with calculations from published refractive indices and with the ratios of the refractions of fatty acids

and triglycerides. The ratio is little affected by the saturation of the acid, being about 0.9938 for stearin, olein, linolin and linolenin, but decreases with the lower acids, palmitin, 0.9922; laurin, 0.9905.

Some typographical errors in reference books are noted, and the published refractive index of the acids of olive oil is said to be low by about 0.0050.

F. R. Eldred, *secretary.*

B. L. MURRAY (chairman's address): *Our Advances and Retrogressions in Pharmaceutical Chemistry.*

A. B. ADAMS and J. M. DORAN: *Smoking Opium: Its Manufacture and Chemical Composition. Exhibit—Samples and Smoking Outfit.*

LINWOOD A. BROWN: *An Improved Method of Assay for Aromatic Sulphuric Acid.*

The total acidity is determined by direct titration, using phenol phthalein and $N/10$ KOH, after which the "free sulphuric acid" is determined by precipitation as $BaSO_4$.

From the $BaSO_4$ found is calculated the number of c.c. of $N/10$ H_2SO_4 equivalent thereto. This is subtracted from the number of c.c. $N/10$ KOH consumed by total acidity, the difference represents the acidity due to the ethyl sulphuric acid, and from this is calculated the equivalent amount of H_2SO_4 .

The U. S. P. method gives too low results, due to the fact that ethyl sulphuric acid is not entirely hydrolyzed on heating for four hours, while in this method the results are higher, closely approaching the theoretical amount of H_2SO_4 known to be present.

Comparative tables of results by the two methods are given.

H. C. HAMILTON: *Notes on Cannabis Indica.*

The paper reviews the more important publications on the chemistry and pharmacology of the drug and describes a process of obtaining a body which possesses high activity.

This substance was not examined chemically, but its physical properties and physiological reactions were investigated and described. It is similar to that of Wood Spivey and Esterfield known as Cannabinol, but is obtained by a different method. No chemical treatment was ca-

pable of separating it into an active and an inactive portion.

Physiologically it was found to produce the typical "Cannabis intoxication" with a smaller dose than any other derivative of the drug so far obtained.

The paper concludes with comments on the peculiarities of this drug, which apparently make it unreliable. This is shown, however, to be due largely to the characteristics of the person on whom the effects are observed and not often, as is commonly supposed, to the variability in the drug itself.

H. C. HAMILTON: *The Pharmacopæial Requirements for Cannabis Sativa*.

The U. S. P. requirements are such that commercial samples of this drug can rarely be used as official because the drug has so often passed to the fruiting stage before being gathered, while to specify that it must be grown in India results in excluding a drug of first class quality grown in other localities.

To remedy this it is suggested that the requirements be made partly chemical and partly physiological. *Cannabis Sativa* is botanically identical from whatever locality it comes. Moreover, the extract soluble in cold alcohol is the active part and the yield of this can readily be determined.

Since the yield of an extract of this character is one of the variable factors and its activity the only other factor of importance the proposal is that the standard for *Cannabis Sativa* be that it shall contain not less than 10 per cent. extractive soluble in cold 95 per cent. alcohol. Further, that this extract must react on susceptible dogs when administered internally in a dose of 10 mg. per kilo weight of the dog.

JOSEPH P. REMINGTON: *Progress on the Work of Revision of the United States Pharmacopæia*.

The American Chemical Society, having representation in the United States Pharmacopæial Convention, should be informed of the progress made from time to time in the work of revision. The sub-committee on scope have made their report and a tentative list of admissions and deletions has been printed in the public magazines and journals. The Pharmacopæia is a book of standards. The necessity for careful and thorough revision. Analytical chemistry the foundation stone in the building of reform structures. The influence of the Food and Drugs Laws on the United States Pharmacopæia. The plan of revision. The American Chemical Society invited by

the chairman to send comments, facts and suggestions to aid in the work.

A. D. THORBURN: *The Estimation of Morphine in Cough Syrups*.

A. ZIMMERMAN: *Laboratory Studies of Rennin*.

A study of the properties of this ferment, when prepared by different methods. The variation in the length of time required to curdle different specimens of milk by rennin and how this is influenced by the milk, according to the length of time it is kept after the milking. Standardizing rennin to use as a control in rennin assay, for more accurate results. The acceleration of the action of rennin upon milk by phosphoric acid. The effect of alkalies upon milk, causing a variation of the length of time required to curd milk by rennin. The influence of heat in changing the acidity of milk, kept for a varied number of hours after the milking.

C. M. FENCE: *The Bromine and Iodometric Methods for the Volumetric Determination of Cresol*.

Usual bromine methods for determination of cresol depends upon fixed conditions predisposing a previous knowledge on the part of the operator, and while they may be of service they do not satisfy the demand for a desirable method.

Tri brom o. and p. cresol brom compounds can not be formed in a manner analogous to the production of 2-4-6 tri brom phenol brom. Di brom cresol brom compounds are formed and finally tri brom phenol brom; however, o. and p. cresols can not be determined volumetrically by a conversion into these compounds.

Meta cresol is determined by a conversion into tri brom m. cresol.

O. and p. cresols from di iodo compounds and this reaction is made the basis of a method for their determination.

Meta cresol does not yield di iodo compounds under the same conditions; hence, cresol U. S. P. or any mixture containing m. cresol can not be determined by a volumetric iodine method.

L. E. SAYRE: *The Analysis of a Very Old Sample of Powdered Gelsemium Root*.

ATHEFTON SEIBELL: *A Bromine-hydrobromic Acid Method for the Determination of Phenols*.

CHARLES BASKERVILLE and W. A. HAMOR: *The Impurities of Anæsthetic Chloroform and Methods for their Detection*.

The impurities which anæsthetic chloroform brings with it from the manufacturer ("organic impurities") and the oxidation products of chloroform and alcohol are considered chemically

and physiologically, and rigid methods are given for their detection and estimation. "The main impurities contained in American anæsthetic chloroforms are, besides water, impurities decomposable by sulphuric acid and traces of the oxidation products of ethyl alcohol." The comparative purity of various samples of chloroform is discussed, and the necessary precautions which should be taken by manufacturers to guard against contamination are given. It is pointed out that "serious results have occurred from the use of anæsthetic chloroform containing foreign substances, and (that) although the grades at present sold as chloroform for anæsthesia hardly contain impurities which can be held responsible *per se* for deaths which have occurred during narcosis, yet the presence of these may produce some, at least, of the disagreeable after-effects so often noticeable following the administration of some chloroform." Results are given which lend strong support to the view of the authors as to the nature of the oxidation of chloroform and as to the rôle of alcohol in preservation.

M. I. WILBERT: *The Influence of Patents and Trade-marks on the United States Pharmacopœia.*

J. B. WILLIAMS: *The Estimation of Morphine in Pills, Tablets, etc.*

Morphine is more soluble in a mixture of alcohol and chloroform than in either solvent alone.

The aqueous solution of the sample containing morphine is made alkaline and extracted with a mixture of alcohol and chloroform, the alkaloidal solution evaporated to dryness dissolved in volumetric acid and titrated. Estimations can be made in from 2 to 3 hours.

Comparative results with Thorburn's phenyl-ethyl alcohol method are in favor of the alcohol-chloroform method.

FRANK O. TAYLOR: *Note on Mastix and Sandarac.*
C. H. BRIGGS: *The Alcohol Requirement of the Pure Food and Drug Law and the Accuracy of Alcohol Assays of Pharmaceutical Preparations.*

To meet the requirements of the Pure Food and Drug Law, all pharmaceutical preparations must be assayed for alcohol. Alcohol assays are apt to vary for several reasons. Volatile oils and drug extracts tend to give low results.

A ruling to the effect that fluid extracts and elixirs could be labeled with the maximum content of alcohol is very desirable.

FRED. KLEIN: *A Laboratory Study of Vegetable and Mineral Oils.*

FREDERICK J. AUSTIN: *Comments on Tests of the U. S. Pharmacopœia—Eighth Revision.*

Sets forth the discrepancies in the two tests for iron applied to copper sulphate, the apparent necessity of a time-limit in the test for absence of petroleum benzin, kerosene or similar hydrocarbons in oil of turpentine, the necessity of using larger amounts of hydrochloric and nitric acids in determining whether these acids are sufficiently free from arsenic for reagent use, and the unreliability of the U. S. P. test for absence of oxychloride in solution of iron chloride as an indication of whether it is suitable for use in making the U. S. P. tincture of iron chloride.

R. NORRIS SHREEVE: *Suggested Modifications to the U. S. P. Assay of Opium.*

Some samples of opium were cited in case of which the U. S. P. assay will not remove but about two thirds of the morphine. So it is suggested that a very vigorous mechanical agitation be given the opium, and that a test be applied to determine the completeness of the extraction of morphine.

It was shown that the U. S. P. alcoholic mother liquors retain up to 100 milligrams of morphine, and to determine this it is suggested that a blank precipitation be made on pure morphine.

To determine the purity of the crude morphine the Mallinckrodt reassay is recommended.

W. O. EMERY: *Estimation of Antipyrine in Acetanilid or Acetphenetidin Mixtures.*

W. O. EMERY: *Estimation of Codein in Acetanilid or Acetphenetidin Mixtures.*

L. F. KEBLER and C. H. KIMBERLY: *Standard for Tincture of Ginger.*

An examination of a number of samples of tincture of ginger also at times designated extract of ginger shows that there was a material variation. Tinctures of ginger from the best manufacturers were then purchased and examined. The Pharmacopœia gives a process for manufacturing this article but does not give a specific standard, neither is the variety of ginger to be employed indicated. The latter is interpreted to mean that any kind of ginger may be used. It was therefore decided to purchase representative available samples of the various gingers on the market and use them in the manufacture of tincture of ginger. A description of the samples together with their fineness is outlined in the paper. The preliminary

examination showed that the available samples of Calcutta and Japanese ginger were not of a character suitable for manufacturing the tincture. Tinctures were then made from all of the samples and it was found, as indicated by the analysis, that the Calcutta and Japanese gingers produced tinctures of inferior character. The standard arrived at was as follows: Specific gravity, 0.8200; alcohol, not less than 88 per cent.; non volatile matter, between 1.25 per cent. and 1.75 per cent.

E. O. EATON: *Estimating Small Quantities of Morphin in Mixtures.*

At the 27th annual convention of the Association of Official Agricultural Chemists, a method for determining small quantities of morphin in mixtures was presented.

The method in brief consists in extracting the morphin from the mixture by means of lime water which is subsequently treated with ammonium chloride, the morphin precipitated, removed with a chloroform-alcohol mixture and the morphin finally determined volumetrically.

During the past year, two mixtures and a sample of opium were submitted to several workers and the results and their observations recorded. In the case of the two mixtures, several workers' results agreed fairly well, but the results obtained with the opium were quite unsatisfactory.

A. G. MURRAY: *Estimating Small Amounts of Nitroglycerin.*

L. F. KEBLER: *Standards and Methods.*

In this paper attention was called to the necessity of carefully studying present available methods and standards. It has been found from time to time that the methods prescribed for arriving at a certain standard are defective and therefore unsuited for careful court work. Particular attention was called to the shortcomings of the present method for determining the alkaloidal content of henbane leaves. The method, as a rule, gives results below the actual content of alkaloidal matter.

The subject of standards was referred to and several specific cases quoted: For example, the standard for cannabis indica is prescribed as a product free from stone cells, which means virtual absence of seeds. Experience shows that it is practically impossible to find such a product on the market. Its enforcement, therefore, would be a most difficult problem. The question of arriving at a fair and just standard was also taken up and discussed fully. For example, the Pharmacopœia

prescribes a definite standard for hydrogen peroxid, but it is well known that this commodity is prone to decomposition and the question arose as to what amount of variation should be permitted before considering the article inferior. In order to determine this point, all of the available samples of hydrogen peroxid were purchased and examined by two different observers in several sections of the country. The observations were made during a period extending over one year, and it was found that there was no difficulty whatever in preparing this commodity so as not to fall materially below 15 per cent. of the prescribed standard within six months. If, therefore, a sample of hydrogen peroxid was found to be only one half the strength prescribed by the Pharmacopœia, it was either made by faulty methods or much more time than six months had elapsed since its preparation. Other examples were cited to show that it was absolutely necessary to use judgment and discretion even though the standard was prescribed.

DIVISION OF ORGANIC CHEMISTRY

Geo. B. Frankforter, *chairman.*

Wm. J. Hale, *secretary.*

WILLIAM A. NOYES and J. A. COSS: *The Decomposition of Nitroso Compounds.*

Some years ago Mr. Taveau, with one of us, found that on warming the nitroso derivative of the anhydride of aminolauroic acid,

with an alcoholic solution of sodium hydroxide, a compound was formed to which the formula

was assigned. A study of the similar decomposition of the nitroso derivative of phthalimidine,

has shown that the primary product is a diazo compound of the structure

This decomposes, giving the compound

In the presence of alcohol it gives the ester ether

The first of these is, of course, the analog of the compound described by Mr. Taveau and the latter is the bishydrazone of camphonic acid,

HOWARD W. DOUGHTY: *Ortho- and Para-Tolueneselenonic and Tolueneseleninic Acids.*

NICHOLAS KNIGHT: *The Preparation of Certain Oxy lactones.*

When phenyleyan pyroracemic acid ethyl ester is heated with sulphuric acid, the ester is hydrolyzed and water and carbon dioxide pass out of two molecules of the acid. The resulting product is an oxy lactone of the formula $\text{C}_{17}\text{H}_{14}\text{O}_8$, which melts at 171° .

When a mixture of phenyl pyro racemic acid is allowed to stand some days with fuming hydrochloric acid the liquid becomes filled with fine needles which on crystallizing from alcohol is shown to be an oxy lactone of the formula $\text{C}_{18}\text{H}_{12}\text{O}_8$. The melting point is 206° . A number of salts were made from this oxy lactone.

J. U. NEP: *The Three Lactones d-Mannonic Acid and their Bearing on the Constitution of the Sugars and the Glucosides.*

TREAT B. JOHNSON: *The Action of Halogens on Tyrosinehydantoin.*

Methods have been developed for preparing easily 3,5-diiodo-, 3,5-dibromo- and 3,5-dichloro-tyrosines. Bromine and iodine react smoothly with tyrosine, $\text{HOC}_6\text{H}_4\text{CH}_2\text{CH}(\text{NH}_2)\text{COOH}$, forming 3,5-dibromo- and 3,5-diiodotyrosines, respectively. 3,5-Dichlorotyrosine is not formed in an analogous manner by the action of chlorine on the amino acid.

Chlorine and iodine react with tyrosinehydantoin, forming the corresponding 3,5-dichloro- and 3,5-diiodotyrosinehydantoins, respectively. Bromine reacts abnormally with tyrosinehydantoin, giving 3,5-dibromobenzalhydantoin.

TREAT B. JOHNSON: *The Action of Potassium Thiocyanate on α -Amino Acids.*

The hydantoin derivatives of α -amino acids are well known, and of great value for the identifications of these acids. The corresponding nitrogen-unsubstituted 2-thiohydantoins, however, are not known. A practical method has now been developed by which representatives of this new class

of compounds can be easily synthesized. The 2-thiohydantoin derivatives of glycocoll and alanine have already been prepared.

The present communication is in the nature of a preliminary statement regarding the extension of this work to other α -amino acids, which has already been begun. The results indicate that this class of compounds will be of great value in helping us to develop other syntheses of biological significance.

ALVIN S. WHEELER: *New Thermometers for Accurate Melting-point Determinations.*

The thermometers are of the usual length but are graduated only at the lower end so that the graduations are completely immersed in the liquid of the ordinary melting-point bath, the Thiele for instance. There are seven in the set in order to cover the necessary range. They may be obtained of C. Richter, of Berlin, and standardized by the Reichsanstalt. They have met the approval of some very well known men.

ALVIN S. WHEELER: *The Walden Inversion.*

A model consisting of celluloid balls of various colors attached to corks covered with wire bristles designed to attach same to a large bristle-covered ball, the C atom, was exhibited to illustrate the theory propounded by Emil Fischer to explain the Walden inversion. The case studied by the author with Fischer was that of α -hydroxyisohexic acid. This acid was split into its active forms, the *lævo* being obtained in pure condition. Its ethyl ester with PBr₃ yielded a bromo ester which was strongly dextrorotatory. But the *lævo* acid with NOBr gives a *lævo* bromo acid which yields a *lævo* bromo ester.

R. R. RENSHAW: *Studies in the Methods of Preparation of Diglycerides.*

The reaction between salts of stearic acid and 1,2-dibrom and diiodhydrin have been investigated between the temperatures of 130° and 200° . There is formed stearic acid, distearin tristearin and small amounts of a compound containing bromine and stearic acid. Good yields were never obtained. The use of the lead salt seems to be preferable.

At slightly above its melting point dibromhydrin dissociates completely into two molecules, hydrobromic acid and probably epibromhydrin.

Pure 1, 2-dilaurin, diisovalerin and diacetin have been obtained.

R. R. RENSCHAW: *Investigation of Choline and its Derivatives.* (Third paper.)

By the action of phosphorus oxychloride on choline chloride there has been obtained a highly hygroscopic, unstable chlorcholine phosphoric acid dichloride.

Experiments on the stability of choline salts have been carried out both by physiological and chemical tests. Pure choline salts give a lowering of the blood pressure. Choline chloride is not a very unstable salt. It can be preserved without decomposition into trimethyl amine or neurine.

WILLIAM J. HALE: *The Formation of Nitropyrimidines.*

CHAS. H. HERTY and C. S. VENABLE: *The Schkate-loff Method for Reduction and Precipitation of Resin Acids.*

CARL O. JOHNS: *On 2-Oxy-1-Methylpurine.*

The potassium salt of 2-oxy-5-nitro-6-aminopyrimidine was heated with methyl iodide and a mono-methyl derivative was obtained. The position of the methyl group was ascertained by converting this compound into 2, 6-dioxy-3-methyl-5-nitropyrimidine. When 2-oxy-3-methyl-5-nitro-6-aminopyrimidine was reduced with ferrous hydroxide it gave 2-oxy-3-methyl-5, 6-diaminopyrimidine, which in turn gave a formyl derivative the potassium salt of which, when heated, formed the potassium salt of 1-methyl-2-oxypurine. The free base crystallized with 2 molecules of water. The picrate decomposed at 214° C.

CARL O. JOHNS: *On 2-Oxypurine and 2-Oxy-8-Methylpurine.*

2-Oxy-5, 6-diaminopyrimidine was heated with formic acid and a monoformyl derivative was produced. The potassium salt of this compound liberated water when heated and the potassium salt of 2-oxypurine was produced. The free base crystallized with one molecule of water and the crystals were stable at 110° C., but the water escaped at 130° C. The picrate decomposed at 245° C.

Acetic anhydride reacted with 2-oxy-5, 6-diaminopyrimidine and the chief product was a mono-acetyl derivative. The potassium salt of this was heated and the potassium salt of 2-oxy-8-methylpurine was obtained. The nitrate decomposed violently at 205° C. and the picrate at 250° C.

M. L. CROSSLEY: *A New Derivative of Anthraquinone.*

M. T. BOGERT and M. HEIDELBERGER: *Phthalones in the 4-Quinazolone Group.*

2-Methyl-4-quinazolone condenses smoothly with phthalic anhydride to the symmetrical phthalone, which behaves as a weak acid, forming a yellow mono-sodium salt and a red disodium salt, as well as a red mon-anil, a mono-phenylhydrazone and a sulfonic acid. Energetic reduction converts the phthalone into the corresponding hydrindone. Bromination of the sulfonic acid of the phthalone in aqueous solution yields a dibrom 2-methyl-4-quinazolone, which is not the 6, 8-dibrom compound, a pentabrom 2-methyl-4-quinazolone, a monobrom 2-methyl-4-quinazolone sulfonic acid, phthalic and sulfuric acids. An interesting feature of the reaction is that the bromine splits the phthalic acid off from the quinazolone.

6-Nitro and 7-acetamino 2-methyl-4-quinazolone condense similarly to phthalones. With phthalimide, the 2-methyl-4-quinazolone condenses to the unsymmetrical, or beta, phthaline, with formation of a small amount of what appears to be a bis-quinazolone phthaline.

2-Methyl-4-quinazolone and succinic anhydride react vigorously with production of a tarry mass, from which a colorless anhydro body may be isolated.

2-Methyl-4-quinazolones carrying alkyl groups in position 3 either refuse to condense with phthalic anhydride or give but small yields of phthalone.

In none of the experiments was the formation of any isophthalone observed, nor could we isolate any intermediate products except the phthalate of the quinazolone.

Like the quinophthalones, these phthalones act as yellow dyestuffs, but in tinctorial power they seem inferior to the former.

M. T. BOGERT and G. A. GEIGER: *On Certain New Quinazolines.*

The following new 4-quinazolones have been isolated and studied: 3-ethyl; 3-benzyl; 2-methyl-3-p-nitrophenyl; 2-methyl-3-p-tolyl; 2-methyl-3-alpha-naphthyl; 2-methyl-3-beta-naphthyl; 6-nitro; 6-amino; 6-acetamino; 6-nitro-3-methyl; 6-amino-3-methyl; 6-acetamino-3-methyl; 6-nitro-3-ethyl; 6-amino-2, 3-dimethyl; 6-nitro-2-methyl-3-ethyl; 6-amino-2-methyl-3-ethyl; monobrom and brom-2-methyl.

The 3-methyl-4-quinazolone of Knape (m.p. 71°) carries a molecule of water of crystallization, the pure anhydrous substance melting at 105°.

Nitration of 2-methyl-3-phenyl-4-quinazoline with a mixture of concentrated sulfuric and fuming nitric acids gives a dinitro derivative; by similar treatment of 2-methyl-3-p-nitrophenyl-4-quinazoline, only one nitro group is introduced; but these two dinitro derivatives are not identical. Nitration of 2-methyl-3-p-tolyl-4-quinazoline also gives a dinitro derivative. The action of nitric acid, in presence of metallic mercury, upon 2-methyl-4-quinazoline gives only the mercury salt of the latter, whereas with quinoline a nitro-hydroxy derivative is produced.

The 4-quinazolones are not readily brominated, but by the Juvalta process bromine derivatives may be obtained.

M. T. BOGERT and G. A. GEIGER: *On Quinazoline Iodomethylates.*

Iodomethylates, and other iodoalkylates, have been prepared from a large number of quinazolines, and the following general conclusions are drawn from the experiments:

1. 4-Quinazolones add alkyl iodides generally only under pressure at about 110°.

2. The alkyl iodide adds to the N adjacent to the benzene nucleus (*i. e.*, the N in position 1 in the quinazoline nucleus) and not to the N in position 3, since the compounds obtained by adding methyl iodide to 2-methyl-3-ethyl-4-quinazoline and ethyl iodide to 2, 3-dimethyl-4-quinazoline are not identical.

3. The iodoethylates are more soluble in water, and in methyl alcohol, than the iodomethylates.

4. By the action of methyl iodide alone, in excess, 4-quinazoline, 3-methyl-4-quinazoline and 4-methoxyquinazoline, all give one and the same product, namely, the iodomethylate of 3-methyl-4-quinazoline.

5. Many of the nitro 4-quinazolones refuse to combine with methyl iodide.

6. Styryl 4-quinazolones add methyl iodide more readily than ethyl iodide, but certain groups in position 3 appear to prevent the combination even with methyl iodide.

7. By the action of silver nitrate upon some of these iodomethylates, corresponding methyl nitrate addition products have been obtained.

M. T. BOGERT and L. E. WISE: *On p-Aminobenzonitrile.* (Third paper.)

The following additional compounds have been prepared and studied: p-aminobenzonitrile picrate, p-cyanoxanilamide, oxanilic p-cyananilide, p-cyan-succinanilic acid, its silver salt, methyl and ethyl

esters, and anil, p-cyanphthalanilic acid and its anil, p-cyanphenylurethane, p-caramido phenylurethane, p-cyanphenyl urea, carbanilic p-cyananilide, p-cyan-carbanilide, methylene di(p-cyanphenamine), 3-nitro-4-acetaminobenzamide and 3, 4-di-acetyldiaminobenzonitrile.

The nitrile appears to add a molecule of chloral directly, and then on dehydration gives the trichlorethylidene di-p-cyanphenamine.

Bromination of the acetamino nitrile, like nitration, gives the mono substitution product.

From 3, 4-diaminobenzonitrile, the 3-cyan-alpha-methyl benzimidazole can be obtained as well as the corresponding amide.

M. T. BOGERT and G. D. BEAL: *A Further Study of the Stilbazoles, Hydrazones and Schiff Bases in the 4-Quinazoline Group.*

In the condensation of aldehydes with alpha-methyl pyridines or quinolines, the alkynes evidently form easily and are often so stable that considerable difficulty is experienced in dehydrating them to the stilbazoles. With these quinazoline condensations, on the other hand, the alkynes either do not form at all or are so unstable that they immediately lose water and give the stilbazole. Neither hydrogen nor bromine can be added to the double bond of these stilbazoles, but bromine gives rise to substitution products.

A large number of new aldehyde condensation products were prepared of the above types. Most of the styryl quinazolones are pale yellow and crystallize in fluffy masses of short silky needles. Often they show strong tribo-electric properties. Those with a free hydrogen atom in position 3 usually dissolve readily in solutions of the caustic alkalies and are reprecipitated by carbon dioxide.

Incidentally, a number of new quinazolines were prepared by condensing various amino bodies with acylanthranils, and certain of them were tested with reference to their physiological effect upon animals.

Under the conditions of our experiments, the group which reacted most readily with aldehydes was the 3-amino group, then the 2-methyl, then the 7-amino, while the 2-amino refused to condense at all. Benzaldehyde proved much the easiest aldehyde to condense with these groups, often reacting when all other aldehydes tried failed.

M. T. BOGERT, R. A. GORTNER and A. H. KROFF: *On Certain New Dyestuffs.*

By condensation of acylanthranils with aromatic primary diamines, new amine bases result which can be used for the production of dyestuffs

in much the same manner as the anilines or naphthylamines.

This paper describes only certain of the azo dyes obtained from these new quinazoline bases, together with a few other related dyestuffs. The dyes described are (A) those obtained by diazotizing aminoquinazolines, with the amino group either on the benzene or on the miazine portion of the nucleus, and coupling with various well-known couplers; and (B) those obtained by using these new bases themselves as couplers for the ordinary diazo salts.

Monazo and polyazo dyestuffs can thus be produced in infinite variety. Those obtained from acylamino acylantranils may be de-acylated and the liberated amino group again diazotized and coupled.

These new dyes include direct dyestuffs for cotton, as well as for wool and silk. Many are fast to light, acid or alkali, washing and milling, bleaching, etc.; they penetrate the fiber well and give level dyeings.

WM. MCPHERSON and CECIL BOORD: *The Preparation of Orthoquinones with Complex Side Chains and Their Reactions with Hydrazines.*

E. K. MARSHALL, JR., H. C. ROBERTSON, JR., and Miss J. PEACHY HARRISON: *On the Mechanism of the Reactions of Ethylates with Alkyl Halides.*

N. E. LOOMIS, C. N. MYRES and S. F. ACREE: *The Use of the Hydrogen Electrode in Organic Chemistry.*

RALPH H. MCKEE: *The Preparation of Sulfonic Acids.*

The process of sulfonating aromatic hydrocarbons can be greatly facilitated by the use of vigorous stirring, *e. g.*, cymene with slightly more than its own volume of sulfuric acid (sp. g. 1.42) gave at room temperature in twenty minutes complete sulfonation, where by the use of infusorial earth it requires several days, or shaken by hand on the water bath with much excess of acid it requires a number of hours. The stirrer used rotated 900 times a minute.

Paraffin hydrocarbons, the portion boiling about 200° from ordinary kerosene, stirred with ordinary sulfuric acid at room temperature was partially attacked to give a disulfonic acid. With the fuming acid the hydrocarbon was all attacked with formation of a mixture of sulfonic acids and oxidation products. Strong nitric acid by similar treatment also attacks the paraffin hydrocarbons at ordinary temperature, but the products formed have not as yet been analyzed.

The distinction between the hydrocarbons of the benzene and methane series toward sulfuric and nitric acids shows evidence of being due in large part to the less solubility of the paraffin hydrocarbons in acids rather than to an essentially different chemical character, *i. e.*, the difference is in part one of physical properties (solubility) rather than one of chemical properties.

BIOLOGICAL CHEMISTRY SECTION

Carl L. Alsberg, *chairman.*

I. K. Phelps, *secretary.*

W. M. CLARK: *Gases of Swiss Cheese. II.*

Since the gas formed in Emmental cheese is the immediate cause of the formation of the characteristic "eyes," it was hoped that data concerning the gases produced would aid in diagnosing the bacteria which are thought to be responsible for the development of the eyes.

For this purpose apparatus was devised for collecting the gases found in the "eyes" and in "pin holes" and the body of the cheese. It was found that the gas of normal eyes consists largely of CO₂ and nitrogen. Hydrogen is sometimes present in very small percentages. The abnormal production of gas which takes place frequently the first day was found to be accompanied with large percentages of hydrogen.

The gas produced by normally developing cheese during the period of its maximum eye-formation was found to be chiefly CO₂.

The absorption of oxygen was studied as well as the permeability of cheese to different gases.

In the light of all the facts thus gained a discussion is made of the interchange of gases and of the relation of these to theories concerning the formation of the eyes.

L. W. FETZER: *The Cholesterol Content of Milk under Normal and Pathological Conditions.*

From this work it can be noted that a decrease in the cholesterol content of milk takes place under pathological conditions, and where a decrease in cholesterol content was noted there was a corresponding decrease in the fat content. If, however, the cholesterol content was compared with the milk fat on the basis of 100 parts of ether extract, then the cholesterol seemed to be increased.

J. P. ATKINSON: *Quantitative Results of Certain Poisonous Metals and Alkaloids after Digestion of their Enveloping Tissue in Artificial Gastric Juice.*

E. D. CLARK and F. J. SEAVER: *Studies on Soils Subjected to Dry Heat.*

In the present paper we have extended to the green plants our earlier observations of the effects of heated soils upon the growth of fungi. Different degrees of dry heat give soils whose aqueous extracts have a brown color the depth of which is proportional to the intensity of the heat. The amount of soluble matter, organic, inorganic, nitrogen, etc., was also proportional to the different temperatures (90° to 180° C.). The dark extracts from strongly heated soils were favorable for fungous growth but were distinctly unfavorable to Lupin seedlings grown in them; this inhibiting action being greatest in the darkest colored extracts. Oats sown in a series of soils heated to different temperatures showed a slight stimulation for the temperature up to 125°, when compared with the unheated soil as a control; while above 125° the heated soil had a very toxic effect. The organic matter of the darker extracts gives nearly all the tests for reducing sugars, is largely precipitated by acetone, smells like caramelized sugar, and has a strong acid reaction to litmus.

R. H. JESSE and EDWARD BARTOW: *Composition of Gases Formed by the Decomposition of Organic Matter.*

We were called upon to investigate the cause of an explosion of gases in a septic tank at Highland Park, Illinois. In trying to trace the cause of this explosion we collected and analyzed gases from several septic tanks. But little variation was found between the composition of the gases from the tank which exploded at Highland Park and the gases from other tanks in the central west. There was, however, a great variation between the composition of these gases and the reported composition of gases analyzed by other investigators. During the summer of 1911 samples of gases were collected and analyzed from tanks in Illinois, Columbus, Ohio, from Worcester, Massachusetts, and from the Illinois River below the mouth of the Drainage Canal. The greatest difference is seen in comparing the gases from Worcester with the gases from Illinois tanks. The gases from the Illinois River agree closely in composition with the gases from some of the septic tanks and differ very materially from a sample of gases collected from an unpolluted swamp. We have noted differences in gases taken from different compartments of the same tank and there is an apparent difference in gases collected below the upper sludge and in the bottom.

We feel that the results thus far obtained can only be regarded as preliminary to further study of the subject.

F. D. CLARK and R. A. GORTNER: *The Chromogen and Associated Oxidases in the Mushroom *Strobilomyces strobilaceus*.*

L. A. HAWKINS: *The Effect of Certain Chlorides Singly and Combined in Pairs on the Activity of Malt Diastase.*

R. A. GORTNER and E. D. CLARK: *The Chromogen and Associated Oxidase in the Mushroom, *Strobilomyces strobilaceus*.*

Upon injury the color change of this fungus is from white through pink to black, this action being a rapid one. We considered that this was a case of ordinary tyrosinase activity and it was only upon examining the material for another purpose that we learned that this assumption was not true. We were unable to detect the slightest trace of free tyrosin by any of the delicate color tests. However, we were able to make preparations of an oxidase from this plant that were very active in causing the oxidation of a tyrosin solution. Evidently, then, this fungus contains a tyrosinase or similar enzyme which oxidizes some other chromogen. This chromogen proved to be pyrocatechin or one of its derivatives, as shown by all the tests and methods at our disposal. The oxidase preparation produced exactly the same change in a solution of pure pyrocatechin that is noticed in the plant itself.

H. H. BUNZEL: *Biochemical Study of the Curly-top Disease of Sugar Beets.*

The paper gives results obtained in oxidase measurements on diseased and healthy beets, on leaves as well as roots, under the various conditions at different times of the day and various stages of development. The result obtained in greenhouse experiments, i. e., that the diseased leaves have a higher oxidase content than the healthy ones, was confirmed in the field. The general result of all the experiments carried out, indicates that the oxidase content is higher in the leaves in all the cases where the normal growth of the plant has been interfered with, whether the retardation of growth is brought about by excessive drought, excessive watering of the soil, the curly-top disease or other diseases. The distribution of the oxidase in the leaves and roots of the plant was measured. Analyses of the samples collected simultaneously with the oxidase determinations are as yet not completed.

C. L. ALSBERG and O. F. BLACK: *Phytochemical Studies in Cyanogenesis*.

The relation between the nitrates in the soil, nitrification during drought and cyanogenesis in sorghum, based on experiments done at the Arlington Farm in the course of the past summer, is discussed and an incidental error in the common method of determining hydrocyanic acid in plants is pointed out.

C. L. ALSBERG and W. M. CLARK: *Notes on the Blood of Limulus polyphemus*.

P. A. YODER: *The Presence and Identification of Choline in Wheat and Cotton Seed Flours*.

OSWALD SCHREINER and J. J. SKINNER: *The Action of Nucleic Acid and its Decomposition Product on Soils and Plants*.

Nucleic acid as well as some of its decomposition products occur in soils and the effect of some of these compounds has been studied with wheat seedlings. Mineral nutrient solutions with phosphate, potash and nitrate in varying proportions were used, and to these were added 50 parts per million of the compound tested. The neutralized nucleic acid as well as its nitrogenous decomposition products, hypoxanthine and xanthine, had a beneficial action on the plants, promoting growth and decreasing the nitrate absorption. The plants appear to be able to utilize these compounds directly in their metabolism and require under these circumstances less nitrate for maximum growth.

M. X. SULLIVAN: *Origin of Creatinine in Soils*.

Of samples of the same soil planted and unplanted kept side by side in the greenhouse, the water and glycerine extracts of the planted soils gave larger amounts of creatinine by the creatinine zinc chloride method. It would seem that the increase in the amount of creatinine was connected in some way with plant growth. Creatinine was found in small amounts in the water in which wheat seedlings had grown, in wheat seeds, wheat seedlings, wheat bran, rye, clover, alfalfa, cowpeas and potatoes. Besides the possible production of creatinine by microorganisms and the introduction into soil in the animal excreta of stable manure, the creatinine of soils has its origin in vegetable matter.

EDMUND C. SHOREY: *Nucleic Acids in Soils*.

Nucleic Acids have been obtained from soils by extraction with dilute sodium hydroxide, neutralizing and concentrating under reduced pressure, acidifying with acetic acid and addition of several volumes of alcohol as a light-colored amorphous

body which on hydrolysis gave pentose sugars, purine bases, pyrimidine compounds, levulinic acid and phosphoric acid. Xanthine and hypoxanthine were identified among the purine bases and cytosine among the pyrimidine compounds.

AUBREY V. FULLER: *The Biological Oxidation of Sodium Arsenite in Solution*.

The author has shown that sodium arsenite in solution may undergo practically complete oxidation to arsenate through the agency of a micro-organism or—organisms as yet not identified. The organisms differ from the nitrifying bacteria of Winogradsky in that this activity is evidenced only in the presence of ordinary culture media, such as meat infusion.

C. F. LANGWORTHY and R. D. MILNER: *An Improved Form of Respiration Calorimeter and its Use for the Study of Problems of Vegetable Physiology*.

W. E. TOTTINGHAM: *The Influence of Bacteria on the Soluble Phosphorus of Manures*.

Relevant to a project embracing study of reactions between farm manure and reinforcing substances, such as feldspar, rock-phosphate and peat, investigation of fermenting manures has shown in all cases decrease of water-soluble phosphorus. Fermenting mixtures of manure and rock-phosphate have shown greater decreases than manure alone. A typical experiment with mixed cow and horse manure fermented six months without and with rock-phosphate (25 lbs. fresh manure and $\frac{1}{2}$ lb. rock-phosphate) involved 16.45 grams soluble phosphorus in the manure and 18.49 grams in the phosphate mixture at the start. The water-soluble phosphorus of the manure decreased from 86.7 per cent. to 65.6 per cent. of the total, a decrease of 24.3 per cent. of the original water-soluble phosphorus. The sample with phosphate gave a decrease from 34.3 per cent. to 14.7 per cent. of the total phosphorus, a loss of 57 per cent. of the water-soluble phosphorus. Common solvents for inorganic phosphates, such as carbonated water, ammonium citrate solution and N/5 nitric acid recovered the depressed phosphorus only partially.

Two and one half months standing with and without antiseptics produced the following changes of water-soluble phosphorus in manure-rock-phosphate mixture. Normal fermentation; decrease from 33.26 to 17.64 per cent. of total. Saturated with chloroform; decrease from 32.61 to 28.11 per

cent. Saturated with formaldehyde; decrease from 29.36 to 26.85 per cent. The losses amounted to 47.0, 13.8 and 8.5 per cent., respectively, of the water-soluble phosphorus. The results seemed to indicate that the losses observed were not due primarily to "reversion" of inorganic phosphates, but chiefly to bacterial activity.

Manure bacteria grown on media prepared from extract of fresh manure-rock-phosphate mixture reduced the soluble phosphorus of the media 23.8 to 63.6 per cent. Fresh intact bacterial cells of specific organisms and manure flora contained 34 to 53 per cent. of their phosphorus in water-soluble form. Drying in vacuo at room temperatures did not alter the solubility of the phosphorus appreciably. The residual phosphorus was partly recovered from crushed cells by water and did not appear especially resistant to 0.2 per cent. acid or alkali solvents. These results appear to point conclusively to bacteria as the chief cause of loss of soluble phosphorus in fermenting manures.

Further work is in progress with acid-phosphate and involving also the rôles of soil organisms and the plant in rendering phosphorus of manure bacteria available to crops.

JOHN H. LONG: *A Series of Complete Urine Analyses.*

This paper is a study of the urine of a number of men in normal health and on a protein diet amounting to from 70 to 88 grams daily. The results, presented in tabular form, embraced determinations of the bases calcium, magnesium, sodium, potassium and ammonium and the important acids present.

For each urine the various acid and basic ions present were reduced to the hydrogen equivalent and these results shown in tables. While there was an apparent excess of acid in each case it was shown that with proper consideration of the probable urate and phosphate combinations some of the urine should exhibit an alkaline reaction toward litmus, as was, in fact, the case.

The results are from the mixed aliquots saved from urines collected through a period of about 35 days, and embraced a study of the nitrogen and other factors as well as the acids and bases.

JOHN H. LONG: *Some Further Studies on the Composition of Feces Fat.*

Some years ago attention was called by the writer to the rather large amounts of organic phosphorus compounds found in the fat of feces studied in his laboratory. This is a continuation of these examinations, and analyses were made of

the fats from the feces of six men collected through long periods. These analyses embraced not only a determination of the phosphorus, but numerous other factors as well. The means of the results obtained show that the phosphatide content of the fat is larger than usually stated in works on physiological chemistry.

OSWALD SCHREINER and J. J. SKINNER: *The Effect of Guanidine on Plants under Different Conditions.*

Guanidine is harmful to plants. The effect of 50 parts per million was tested on wheat seedlings in solution cultures and in soils. The solution cultures consisted of nutrient solutions of varying composition in phosphate, nitrate and potash. The toxicity of the guanidine does not show until the fifth or sixth day, when spots appear on the leaves and soon the plant is completely affected and by the end of the second week the tops fall over. The effect of nitrates in the cultures is especially striking in that the harmful effect first shows itself in the cultures highest in nitrate and spreads gradually to those lower in nitrates and frequently does not appear at all in those cultures which contain phosphate and potash but no nitrate. In other words, we have here the interesting case of a harmful nitrogenous constituent, the harmful effect of which is accentuated by nitrates. Nitrogenous compounds other than nitrates, such as asparagine, creatinine or stable manure, when used in conjunction with guanidine, did not produce the harmful effect noticed with sodium nitrate.

WILLIAM SALANT and J. B. RIEGER: *Further Studies on the Demethylation of Caffeine.*

Studies carried out on rabbits, guinea-pigs, dogs and cats show that demethylation in the carnivora takes place far more readily than in the herbivora, the amounts of caffeine eliminated unchanged by the former being very small. The process of demethylation therefore varies quantitatively as well as qualitatively in the above animals.

C. B. BENNETT: *Note on the Distribution of Inosinic Acid.*

Inosinic acid was isolated and identified from the fresh muscular tissue of pigeons.

L. E. WARREN: *A Note on the Poisonous Properties of Parthenocissus quinquefolia.*

The death of a child after eating the berries of the Virginia creeper was recently noted by the public press. While the recorded instances of poisoning from this plant are very few, an examination of the literature showed that oxalic acid has been found in nearly all parts of the plant.

Its quantity does not appear to have been determined, but, pending further investigation, the plant should be regarded with suspicion.

I. G. McBETH and R. C. WRIGHT: *Certain Factors Limiting Nitrification.*

Two per cent. of glucose and two per cent. of starch disappeared from soil in less than seven days. Cellulose disappeared more slowly. The addition of glucose and starch caused a rapid disappearance of nitrate from eastern and western soils; with cellulose the reduction of nitrate was less rapid.

Two per cent. of fresh horse manure caused only a partial disappearance of soil nitrate. After seven days in eastern soil and twenty-one days in western soil nitrification became active, causing an increase in nitrate.

Nitrification took place rapidly in rotted manure; the addition of five per cent. of cellulose caused rapid denitrification.

Nitrification in the soil is inhibited by carbonates, chlorides and sulphates, the former having the strongest effect and the latter the least effect.

There are certain seasonal variations in the rate of nitrification in soil.

M. O. STAFFORD: *Preliminary Study of Iron Peptonates.*

V. K. CHESNUT: *Estimation of Small Quantities of Pepsin.*

M. LOUISE FOSTER: *A Study of the Decomposition Products of Milk Caused by B. lactis erythrogenes.*

Sterile milk inoculated at room temperature with *B. lactis erythrogenes* gave after a few days a faintly red solution, which on longer standing became blood red with coagulation of the milk. During standing—from two to six months—the red liquid became viscous, then fluid again with the formation of a white granular precipitate. The liquid was alkaline and gave the biochemical tests which showed that the organism had attacked the protein molecule as well as the carbohydrate. From 5 to 8.6 per cent. of the total native protein remained unattacked while the remainder was identified as proteoses and monamino acids. The pigment was extracted with amyl alcohol and precipitated with acetone in clusters of red crystals. Further, colorless crystals with alkaloidal odor were obtained. An enzyme was isolated in the usual way. It was found to coagulate milk, giving

a supernatant liquid acid to litmus. This acidity was found to be due to the presence of acetic and formic acids. No lactic acid was found.

A. D. EMMETT and CARL CHRISTOPHER: *Effect of the Quantity of Protein Ingested on the Nutrition of Animals. V. On the Chemical Composition of the Skeleton of Swine.*

The skeleton of pigs, selected from three lots—fed on low, medium and high protein planes—showed: (a) that the percentage of fat varied with the protein fed; (b) that the per cent. of protein was lowest in the low-fed lot and the same in the other two; (c) that the per cent. of ash and phosphorus seemed to be independent of the feed. With the tibia, femur and humerus bones, their weight, length, diameter, breaking strength and modulus of rupture seemed to suggest that the medium-fed pigs had the most compact and firm bones. The weight of the skeleton was greatest percentagely in the low-fed lot.

A. D. EMMETT and H. S. GRINDLEY: *The Relative Nutritive Value of the Cuts of Beef.*

Comparing the protein and fat content of the

edible meat of the eleven wholesale cuts of beef obtained from three steers—the flank, plate, rib, rump and loin were highest in fat, and the clod, round and shanks in protein. Fat made up from 68 to 92 per cent. of the total calorific value. The energy varied directly as the percentage of fat, ranging from 235.1 calories in the clod to 554.9 in the flank. Comparing the grams of meat required to supply 100 calories from the fat and protein, it takes about half as much of the fatter cuts. The most economic cuts from this standpoint are the chuck, plate, clod and shanks.

E. W. MORSE and L. W. FETZER: *The Present Knowledge in Regard to the Nature of Peach Yellowing Disease.*

Summing up our present knowledge in regard to the disease of peach trees known as yellows, it seems natural to conclude that this is a constitutional disease which is inheritable; that is, the progeny have inherited a hypersusceptibility to the disease. The symptoms of the disease—premature ripening of the peach and the appearance of superficial red spots and streaks throughout the flesh of the same, and a yellowing of the leaves the following spring, etc.—seem to point to the hypothesis that the disease is a metabolic one, due to a disturbance of the equilibrium among the enzymes of the plant. Probably there is a hyper-production of the oxidases and a lesser production of the other enzymes, which are active during the life cycle of the plant.

A. R. ROSE: *The Influence of Phytin on Seedlings.*

Phytin has been found universally present in seeds and by some investigators considered to play a significant rôle in germination and early growth of plants and the growths of animals. Nagaoka, Aso and Yoshida in the Imperial Agriculture College in Tokyo have shown that the phosphorus of plants are less beneficial to plant growth than that from animal scraps and wastes, also that the soluble organic phosphorus gave poorer ultimate results as fertilizer material than lecithans and the various inorganic forms of ortho-phosphates except AlPO_4 and FePO_4 . In view of this, experiments were planned and executed to determine, if possible, what the influence of these phosphorus compounds may be upon the earliest growth of the plants. Lupin seedlings were germinated and afterwards allowed to grow in nutrient solutions, some of which contained a phytin compound, for periods of two or more weeks and the influence on the primary root noted. The results seemed to indicate that the several phytates behaved in the

same manner as the corresponding ortho-phosphates. There was no suggestion of any specific influence of the phytic anion upon the seedlings. The phytin solutions in which the seedlings had grown showed no increase in inorganic phosphorus nor inositol and there was therefore no evidence that the phytase of the seed acted upon the phytin in the surrounding liquid. The author contemplates further experiments along this line.

A. R. ROSE and J. T. CUSICK: *The Influence of Phosphorus Compounds on the Yield and Composition of Goat's Milk.*

A preliminary report of a metabolism experiment, the fifth of a series planned by Director Jordan. The former experiments conducted with cows gave interesting results with respect to the milk flow and composition. There was a consistent increase of fat and decrease of milk volume with the increase of phosphorus over a very low phosphorus ration, and *vice versa*. The other constituents of the milk were not appreciably affected. A recent paper by Fingerling gives results contrary to these conclusions, but he used goats and his rations were of different constituents in the high and low phosphorus periods. The data from this experiment tend to confirm the conclusions of the previous experiments at this station and are not at all in harmony with Fingerling's observations, but the results are not as consistent as were those when cows were used. There is a regular parallelism between the milk flow and the various constituents of the milk, except with respect to the fat. In two of the four periods the fat increased and the milk flow decreased with the increase of phosphorus in the rations; in the other two periods the reverse was true. Further investigations are now in progress at this station.

A. R. ROSE: *The Toxicity of Phytin.*

A series of experiments conducted on rabbits weighing approximately 2 kilograms gave in two cases unexpected results. Feeding five grams of the sodium salt of phytin was followed in one and one half hours by death. Analysis of the stomach and intestinal content yielded almost half of the soluble organic phosphorus administered. Death was therefore apparently due to 3.2 grams and 3.66 grams sodium phytate, or 1.7 grams per kilogram.

Methods used and an improved cage described.

H. M. ADLER: *Vicarious Fat Deposits in Rabbits Chronically Poisoned with Oil.*

A. A. EPSTEIN and S. BOOKMAN: *Studies in Glycolipid Formation in the Body.*

ALBERT A. EPSTEIN: *Contribution to the Study of Blood Serum and Serous Effusions.*

The composition of blood sera varies in disease. The changes which occur require careful analysis in close relation with the pathology of the disease investigated. The relation of disease to the production of changes in the chemical composition of the blood, and, also, the relation of alterations in the blood to the production of disease are subjects requiring special study. The effusions present distinct chemical differences, depending upon the site of their production, the nature of the underlying disease and the chemical composition of the blood.

ALBERT A. EPSTEIN: *Immuno-chemical Studies on Peptones.*

The different peptone fractions seem to be able to alter the different blood elements sufficiently to affect their immunological reactions. This power is not possessed by all the peptones equally, either qualitatively or quantitatively. If we regard the phenomenon of hemolysis by immune serum in the light of a biochemical process, depending upon properties possessed by certain constituents of the serum and the red blood cells, the albumoses and peptones show differences in their behavior toward the elements concerned in the production of hemolysis.

THEO. KUTTNER: *Some Findings in Two Cases of Bismuth Poisoning.*

The urine of patients to whom bismuth subnitrate and bismuth subcarbonate had been administered was found to contain bismuth. It is commonly supposed that the organism does not absorb these bismuth compounds.

W. A. WITHERS and B. J. RAY with the collaboration of R. S. CURTISS and G. A. ROBERTS: *Studies on Cotton-seed Meal Intoxication. I. As to Pyrophosphoric Acid.*

JAMES N. CURRIE: *Studies on the Flavor of the Green Mold Cheeses.*

A study of the volatile fatty acids of the green mold cheeses, Roquefort, Gorgonzola and Stilton, shows that the fat undergoes a marked hydrolysis during the ripening process. This change is doubtless accomplished by a lipolytic enzyme of *Penicillium roqueforti*, which, according to Thom, is concerned in the ripening of all of these cheeses. The characteristic peppery taste of the green mold cheeses may be, at least partially, ascribed to an accumulation of caproic, caprylic and capric acids, or their readily hydrolyzable ammonium salts.

MAX KAHN: *On the Absorption and Distribution of Aluminium from Aluminized Food.*

When biscuits baked with alum baking powder are fed in a mixed diet to dogs, aluminium passes in considerable amounts into the blood.

Such absorbed aluminium circulates freely and tends to accumulate to some extent in the various organs.

Aluminium is partially excreted by the liver in the bile and is also eliminated in the urine.

CHARLES H. SANFORD and JACOB ROSENBLUM: *On the Glycyltryptophan and Tryptophan Tests for Cancer of the Stomach.*

T. B. ALDRICH: *On Feeding Young Pups the Anterior Lobe of the Pituitary Gland. I.*

Seven pups, five females and two males, as soon as weaned were separated into two groups A (4), B (3), weighed and fed on bread and milk only for eight days. They were then reweighed and each pup in group A received daily in addition to his milk and bread diet 50-75 mg. of the fresh desiccated, defatted anterior lobe of the pituitary gland; each in the other group received an equal amount of desiccated, defatted ovary. The pups were weighed usually every fourth day and the weights recorded in tables and charts. The experiment extended over nearly four months. These records show that the controls increased in weight faster than the pituitary-fed pups. One pituitary-fed pup weighed the most; but the group curve shows the controls had much the advantage. These observations are not in accord with Professor Schafer's findings, who found that the anterior lobe stimulated the growth of young rats. Further experiments are necessary to decide whether the anterior lobe has a stimulating action or not on young animals.

JOINT PROGRAM OF THE BIOLOGICAL SECTION OF THE
AMERICAN CHEMICAL SOCIETY AND THE AMERICAN SOCIETY OF BIOLOGICAL CHEMISTS

THOMAS B. OSBORNE and L. B. MENDEL: *Maintenance and Growth.*

WILDER D. BANCROFT: *The Study of Environment.*

When studying the effect of environment on an organism, we must distinguish three distinct things: the direct effect of new external conditions involving no adaptation; the adaptation of the organism to the new conditions; and the possible inheritance of the adaptations. The botanists have not made these distinctions. They consider the change of curvature of tendrils with change of temperature as a case of non-adaptive response, whereas it has no more to do with adaptation than the shortening of a fishing-line when it is wetted.

The problem of the inheritance of acquired characters has been complicated unnecessarily by the arbitrary limitation that the character must be inherited for four or five generations after the organism has been brought back to the original surroundings. Since an organism which responds readily to a new environment will also revert readily when brought back, this definition has probably excluded most of the cases in which the inheritance of acquired characters could be shown. The biologists seem never to have realized that inheritance is primarily a hysteresis phenomenon and should be studied as such.

TREAT B. JOHNSON: *The Synthesis of Thiotyrosine.*

A knowledge of this new amino acid was especially desirable, in order to acquire a more definite conception of the true nature of sulphur combinations in proteins. The acid has been prepared by the application of a new, general method for the synthesis of alpha amino acids and its chemical properties are now being studied.

The most important characteristic of the acid, so far observed, is the fact that it does not give

Millon's test. On the other hand, it gives, on warming the concentrated sulphuric acid, as characteristic color reaction, as the Milton's test is characteristic for tyrosine. This study is one of a projected series on new sulphur combinations which has been planned for the Sheffield Laboratory.

ALFRED DACHNOWSKI: *The Relation of Vegetation to the Chemical Nature of Peat Soils.*

C. L. ALSBERG and O. F. BLACK: *Phytochemical Studies on Hydrocyanic Acid.*

J. H. LONG: *The Definition of Normal Urine.*

Our notions as to what is a normal urine have undergone many changes in the years which have elapsed since the first attempts were made to establish standards.

The same individual, at one time on a high protein diet and again on a low protein diet will excrete urine which will be markedly different in many ways, and yet both will be normal.

Improved methods of examination have shown that hyaline casts are much more frequently present in the urine of healthy men than was suspected a few years ago, and it must be admitted that traces of albumin occur in the urine of men who, from all ordinary points of view, are perfectly well.

The statement as to what constitutes normal urine must take cognizance of these facts, and of the further fact that for each individual there seem to be agencies at work which modify the nitrogen distribution, the acidity and the natural sulfur in ways which we can not account for. In a certain sense each individual has his own standard of normality.

ANDREW HUNTER and MAURICE H. GIVENS: *The Nitrogen Excretion of the Monkey, with Special Reference to the Metabolism of Purines.*

A female monkey (*Cercopithecus callitrichus*), weighing 4.7 kilograms, was maintained for 40 days on a daily ration of 200 c.c. whole milk, 200 grams bananas and 20 grams peanuts. The urine was collected every 48 hours. For the first 16 days the average daily excretion of N was 1.83 grams, distributed as follows: urea, 1.59; NH_4 , 0.028; creatinine, 0.065; allantoin, 0.015; purines, 0.0027; undetermined, 0.13 gram N: or, urea 86.9; NH_4 , 1.5; creatinine, 3.5; allantoin, 0.82; purines, 0.15; undetermined 7.1 per cent. of the total N. Uric acid could not be detected.

During the remainder of the experiment attention was devoted particularly to the metabolism of endogenous and exogenous purines. On seven

normal two-day periods the excretion of allantoin N ranged from 27.0 to 31.8, that of purine N from 4.7 to 10.3 milligrams. On five periods, each interpolated between two normal ones, doses of 0.5, 0.5, 1.0, 1.0 and 2.0 grams sodium nucleate were administered. Of the purine N thus fed 90, 56, 41, 24 and 29 per cent., respectively, of the theoretically possible was recovered in the form of allantoin and urinary purines. Of the amount so recovered 79 to 98 per cent. took the form of allantoin; after the second dose of 0.5 gram 2 per cent., and after 2.0 grams 9 per cent. appeared as uric acid. In normal periods allantoin accounted for 71-87 per cent., in nucleate periods 77-86 per cent. of the total purine-allantoin N. In respect of the ratio between allantoin and purine excretion the species examined resembles the lower mammals rather than man. On the other hand, we did not meet with the almost quantitative conversion of exogenous purines into allantoin, which has been reported for the dog.

H. S. REED and H. S. STAHL: *Oxidizing Enzymes in Certain Fungi Pathogenic for Plants.*

The oxidizing ability of the plant extract is often altered as a result of the invasion of parasitic fungi. The extracts of apples invaded by *Sphaeropsis malorum* show no oxidizing powers whatever. Apples attacked by *Glomerella rufo-maculans* show, on the contrary, a somewhat increased oxidizing ability. When grown in pure culture on synthetic media *Glomerella* develops oxidizing enzymes in certain media but not in others.

WALDEMAR KOCH: *Should the Term Protagon be Retained?*

Data were presented which indicated that the preparations referred to as protagon contain at least three substances: a phosphatid containing cholin, a cerebrosid containing sugar, a complex combination of a cholin-free phosphatid with a cerebrosid to which an ethereal sulphuric acid group is attached. The term protagon can not, therefore, be said to have any chemical significance. The details will be presented in a more extended publication.

WILLIAM J. GIES: *Modified Collodion Membranes for Studies of Diffusion.* (From the Laboratory of Biological Chemistry of Columbia University, at the College of Physicians and Surgeons, New York.)

Lipins and many substances which dissolve in ether, alcohol and similar solvents can be dissolved, in large proportions, in U. S. P. collodion solution.

Such mixed solutions, when treated in any of the usual ways for the production of collodion membranes, yield composite homogeneous products. Lecithin, cholesterol, lard, olive oil, rubber, alcohol-ether-soluble protein, organic pigments, ferric sulfocyanate and many other substances have been incorporated homogeneously in such modified collodion membranes, which show interesting differences in permeability.

MORRIS S. FINE: *A Method for Differentiating between Metabolic and Residual Food Nitrogen of the Feces.* (From the Sheffield Laboratory of Physiological Chemistry, Yale University, New Haven, Conn.)

As a rule the methods previously employed for this purpose have not taken into account the fact that the indigestible materials, *e. g.*, cellulose and hemicellulose such as are present in cereals, legumes, etc., show a marked tendency to increase the elimination of fecal material. The following procedure is believed to offer certain advantages over those hitherto proposed. From the fecal nitrogen accruing from a given diet is subtracted the corresponding value resulting from a non-nitrogenous diet, yielding practically the same amount of feces. Such a non-nitrogenous diet may be conveniently obtained by adding agar agar to non-nitrogenous food whose calorific equivalent does not differ materially from that of the diet under investigation. The result thus obtained represents the amount of nitrogen of the latter diet which has actually escaped utilization.

E. MONROE BAILEY: *Biochemical and Bacteriological Studies of the Banana.*

An earlier study¹ has been extended. Enzymes concerned in ripening processes have been investigated, and in addition bacteriological and chemical examinations of the fruit in various stages of maturation have been made. Amylase, sucrase, raffinase, protease, lipase and peroxidase were detected. Tests for maltase, dextrinase and lactase were doubtful or negative. The inner portions of the pulp of sound fruits appear to be sterile, but the regions of the inner coats of the peel may be sparsely inhabited by bacteria. As ripening progresses, starch disappears and the content of alcohol-soluble sugars and dextrins increases. Maltose could not be detected.

IN his presidential address on "The Dignity of Analytical Work," delivered before the American Chemical Society in 1897, Dr. Charles B. Dudley directed attention to the claims which may be asserted in behalf of analytical chemistry as an important and dignified branch of chemical science, and the necessity for intelligent, careful work on the part of even the routine analyst. From a somewhat different standpoint, Dr. W. F. Hillebrand, of international reputation as an analyst, presented at the Philadelphia meeting of the Society, in 1904, a critical review entitled "Some Thoughts on the Present Conditions of Analytical Chemistry," which was based upon his experience as chairman of committees intrusted with the formulation of standard methods of analysis and the investigation of the causes for the remarkable variation in the results of different analysts examining a given sample of material. He sounded a definite and clear note of warning with respect to the prevalence of a lack of care and intelligence, and ascribed the conditions, in part at least, to faulty training in our educational institutions. Within the past month there has appeared an interesting brochure from the pen of Dr. Wilhelm Böttger, professor at the University of Leipzig, entitled "Der Stand und Wege der Analytischen Chemie," in which he criticizes the too empirical nature of much of the analytical

¹ MSS. intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹ Read at a joint session of the American Chemical Society and Section C of the American Association for the Advancement of Science at Washington, December 27, 1911.

practise of the day and makes valuable suggestions respecting the way out of these conditions.

Dr. Dudley's plea was authoritative and convincing, and attracted much interest when it was made public. Dr. Hillebrand spoke from a fullness of experience and with an earnestness which made his criticism strike home. Dr. Böttger writes from the viewpoint of one who is at home in the analytical field and has also thoroughly familiarized himself with the advances of chemical science in other lines which are closely related to the work of the analyst. Is there, then, an excuse for a fresh homily on the status of analytical chemistry? May I say frankly that, had the pamphlet from Dr. Böttger reached me before the title of this address had been announced and its general outline prepared, I should have been inclined to answer this query in the negative, and may I confess that, since Dr. Böttger can write with greater authority than I on certain phases of the present situation, I shall quote freely from him.

But, on the other hand, it is probable that not many of you have recently read the addresses referred to above, a thing to be strongly recommended at your next opportunity, and it is certainly true that too many of the chemical analysts (not alone the "analytical chemists" in a professional sense) are not putting out a grade of work which is commendable to them. It is not unreasonable, then, that we should take time to survey the field; nor is it true that such a survey will show no signs of improvement from which we may take comfort and courage.

When we consider the relation of analytical chemistry to the other branches of our science, we still face such questions as these: Why is it that analytical chemistry lags behind other branches of chemistry in its scientific development? Why is it that

our journals are so often filled with "new" processes of alleged reliability and usefulness, which never acquire general recognition and which are frequently condemned as worthless by those who attempt to apply or repeat them? Why is it that reports of commission after commission on "standard" methods are published, only to sink into oblivion without awakening any interest or attaining any useful purpose? Why is it that the chemical analysts, as a class, lack the respect which should be commanded by those who are following a profession and practising an art which, in its best estate, calls for a very high degree of intelligence, as well as manual skill? Why is it that chemical analyses have come to be made at prices worse than those of the bargain counter? These are, it appears, all pertinent questions to-day.

It has been frequently pointed out that analytical chemistry has so long been regarded as the servant of the chemist—referred to by Ostwald as the "hand-maiden" of chemistry—that far too much attention has been directed to obtaining large returns for small wages. We have nearly forgotten that this "hand-maiden" herself has a natural comeliness, and have ignored the fact that even a little more encouragement to her to improve her methods and accomplish her tasks more thoroughly would easily fit her to sit at the family table—a privilege, formerly hers, of which she has long been deprived. It is easy to see, as Dr. Böttger points out anew, how, after the days of Liebig, the relegation of analytical chemistry to a subordinate position came about amid the interest attaching, first, to rapid developments in organic chemistry, and later to those in physical chemistry, and especially through its connection with the phenomenal growth of the industries, which demanded "results" and too often have allowed what appeared to

be "good enough" for a temporary purpose to become a permanent standard of attainment. These latter conditions must, however, always be reckoned with, and it is not my purpose to spend time in deploring them, or in regretting the conditions of the past, but to ask what encouragement may be offered to the analyst of to-day and what the outlook is for the future.

My chief criticism of the situation in the recent past would be this: That the chemical analysts, as a class, have failed to take advantage of their opportunities, and that those intrusted with their training are considerably responsible for this situation. Specifically, I mean that too many practising analysts allow themselves to remain in ignorance of the aids to accurate, intelligent work which that branch of chemistry known as physical chemistry, in a broad sense, has contributed, and that, while our students are usually made familiar at some time with much of this material, it is not coordinated with their training as analysts. We train too much for manipulative skill and analytical facility and do not sufficiently educate toward that critical intelligence which enables a man to test his own work, to view it from the outside, as it were, and will not allow him to regard it as satisfactory until he has not only assured himself with respect to such matters as the purity of his reagents or the stability of his glassware, but has also studied the effect of a variation of individual factors and of the chemical conditions, so far as his time will permit. Obviously, a practising analyst can rarely afford the time to make his methods of analysis the subject of exhaustive investigations, but something far less than this, yet considerably more than is too often done, would have prevented many deplorable happenings, including the publication of many unreliable analytical procedures to the be-

wilderment of the entire chemical fraternity.

That the analyst who is ambitious to make the most of his privileges to-day is in a position to obtain a larger measure of aid and comfort than formerly is indicated by an instance cited by Dr. Böttger. He contrasts the work of Professor Clemens Winkler upon the atomic weight of nickel with the later work of Professor J. W. Richards, which showed the figure obtained by Winkler to be in error by 0.3 per cent. Winkler was highly skilled in the technique required for the work which he undertook, and possessed special mental aptitude for the task, as Richards himself has testified. It appears, then, reasonable to conclude that Richards, although similarly equipped, succeeded in attaining greater accuracy than Winkler rather because of his greater ability to recognize those factors which would lead to error than because of greater ability to overcome the difficulties after they had been recognized. Richards had at his command a qualitative and, in some cases, a quantitative knowledge of phenomena, unrecognized until recently, which permitted not only the detection of new sources of inaccuracy, but often enabled him to estimate the extent of the errors involved. He made the knowledge of the day serve his keen intellect to its utmost. He took advantage of his privileges.

But perhaps some of you will say, "This is atomic weight work, not analytical chemistry. Those men are ripe scholars and investigators who can command a knowledge of the advances of their science. All this has little to do with me, a busy analyst, or an unripe scholar." That, however, is just where the issue really lies, and it is because so many have thought and still think that a great deal of the accumulated chemical knowledge in the field of general or physical chemistry is "beyond them"

and is something reserved for the use of those with chemical leisure on their hands, that our progress toward better things is so slow. It is also the reason why a great deal of time is wasted on procedures which are almost without value as soon as any one of the particular conditions (often very far from practical conditions) under which they were tested, is altered. It is not at all a difficult matter to obtain an understanding of at least the meaning, for example, of chemical equilibrium and the laws which apparently underlie equilibrium phenomena; yet there are instances of the publication of processes recommending procedures in defiance of these principles, and a great deal of time is wasted in private because of ignorance of them. An interesting and fruitful application of these principles is to be found in connection with the processes of neutralization and hydrolysis, and in selection of suitable indicators for use with acids and bases of varying strength. Modern research has changed this from a haphazard procedure to one of comparative exactness. The principles are not difficult to follow and, if once mastered, can not fail to render any subsequent work in this field more intelligent and, therefore, more pleasurable.

The phenomena of adsorption, with their attendant annoyances to the analyst, have been widely studied. The results are perhaps less positively helpful than in the case of the indicators, but the material is nevertheless well worth attention and study. Colloids—which probably play an often unsuspected part in our analyses for good or ill—must not be overlooked by the well-informed chemist who would best economize his time and energies, and the simple matter of the best way to wash a filter and its contents, long ago pointed out by Ostwald, are not as familiar as they should be. The spectroscopy and micro-

scope are more useful than formerly, a system of micro-analysis, both qualitative and quantitative, having been developed with the latter instrument; the ultramicroscope may well open up new lines of study with respect to the formation of precipitates, the existence of colloids or the conditions controlling electrolytic deposition; wash-waters may now sometimes be advantageously tested through their electrical conductivity; the refractometer, the nephelometer, the colorimeter, the centrifuge, are all finding extended usefulness, and it is incumbent upon the analyst to understand these instruments, and their underlying principles thoroughly if he is to fully avail himself of their aid.

It is probable that analytical chemistry has been as directly aided by the increased accuracy of solubility determinations as in any other way; and these have largely been made practicable by the development of the physico-chemical methods of measurement. These determinations have made it possible to judge of the greatest attainable accuracy of a precipitation method, and have also made practicable the use of a correction factor in the case of unavoidable losses. The analyst should no longer content himself with the mere thought that such losses are inevitable until he has definite assurance that data sufficient to permit of a reasonably accurate estimation of these losses are not to be found. The values obtained for the solubilities of the various sulphides, which are much more accurate than those formerly available, have alone done a great deal to enable the working out of a more reliable scheme of qualitative detection of the elements, one which is based on scientific deductions, confirmed by careful experimentation, as, for example, in the separation of the sulphides of arsenic, antimony and tin by hydrochloric acid, the separation of zinc from the metals of the

copper group, the complete precipitation of lead and cadmium as sulphides.

It is so much a matter of common knowledge that the chemical changes upon which analytical procedures rest are far better understood, and therefore controlled, because of the fruitful hypothesis of Arrhenius, that no extended statement of this seems necessary in this connection. It may, however, be wise to point out that there is a certain tendency to assume that this theory and its applications constitute "physical chemistry" and that there is reason for complacency when one has acquired a fair understanding of these points. While the foregoing statements are far from complete with respect to those points at which our modern chemistry and physics touch analytical chemistry, it must be evident that the possibilities for assistance are far wider and, indeed, more important than a mere ionic interpretation of chemical changes. For it must be admitted that our knowledge of ionic changes, even in a qualitative sense, is still inexact with reference to many reactions familiar to the analyst, and that the most useful data are those of a quantitative character, to obtain which we must command a knowledge of the wider field of physical chemistry in a broad sense.

Modern investigation has then, especially in the border land between physics and chemistry, given us new tools for our trade as chemical analysts. But it has done still more for us by showing us what it means to use them, and it is here that, as analysts, we should learn our lesson. It is, I think, fair to say that the one fundamental reason why much of the published work of individuals or commissions fails of effectiveness and permanence and, in part, the reason for the lack of respect in which the chemical analyst and his work are held, is the lack of appreciation on the part of

authors of the one-sidedness of the published results, and of the procedures adopted as adequate or as the best obtainable. The pages of our journals are, unfortunately, too largely occupied by descriptions of processes, which are supported by data obtained under but one set of conditions, and applied at most to one or two sorts of materials. These conditions are empirically established and are, in many cases, not such as could be controlled under the necessary routine of analysis of materials of more complex structure. The tests, upon which efficiency is claimed, have often been made with pure materials, and in solutions, the contents of which could be easily adjusted and determined, contrasting in this respect with customary analytical conditions. Many authors of analytical procedures lose sight of the important fact that the success of these procedures, in their own hands, has usually been attained only at the cost of considerable practise and as the result of the observance of a series of, often, apparently minor modifications, which they more or less unconsciously ignore when they describe the process for publication. It is exactly this really inexcusable ignoring of these conditions, on the one hand, and the even more frequent failure to study their influence systematically, on the other hand, which has condemned much of the published material. It is true that the intelligent author is between two fires—on the one hand his desire to help his colleagues, on the other hand, the board of editors who, in these days of many papers, must insist upon reasonable brevity. As one who has seen many manuscripts in this field, may I suggest, especially to the younger authors, that I am sure that, while the editors must insist on the omission, for example, of statements to the effect that it is inadvisable to remove a stirring rod

from a quantitative solution without washing it, and, while they must advise the elimination of tabulated statements of the failures encountered on the road to success, and must, in general, curb a rather natural desire to send a four-page reprint containing two-pages worth of work to one's friends, they will welcome an increased exactness of statement of the controlling conditions of analyses, especially when it appears that these factors have been intelligently studied.

It is too obvious to really need mention, that not all of the published work is faulty, and it is notably true that some of the more recent work is of exceptionally high character and sets an excellent standard toward which analysts in general should strive. Reference will be made to only two well-known publications—those of Noyes, Bray and their associates on the development of a scheme of qualitative analysis on a scientific and exact basis, and the work of Allen, Johnston and Adams on the determination of sulphur as barium sulphate. In both these there has been a systematic study of sources of error and, where apparently unavoidable errors appear, the possibility of correction for them has been carefully investigated as well as the determination of the special conditions under which these errors could be reduced to a minimum. Dr. Bray has stated to me (and this view is confirmed by Dr. Böttger) that possibly the greatest service of physical chemistry is the impetus which the precise methods which have been worked out have given to the more critical study of the sources of error and to their prevention or correction. This, in their opinion, is a greater service than any other single attainment in itself.

It may be admitted that few employed as analysts can hope to obtain so complete an insight into other fields as is possessed

by Noyes, Bray, Böttger or Johnston, and their immediate coworkers. But it is not unreasonable to point out that a much less thorough knowledge would be of enormous assistance and would lead to the prevention of another fault in the point of view of most analysts; namely, the overlooking of the element of compensation of errors in their work. Few things would do more to bring up the character of analytical work than a better appreciation of the fallacies involved in "check analyses" or the false sense of confidence in an approximate summation to one hundred per cent. Just here, I believe, our teachers are often at fault. Every student tends to glorify his "check analyses," too often even to the destruction of his professional integrity. Even when there is no question of honesty involved, there is a blind faith in their infallibility, and this is reflected in much of the published work. The idea that two analyses carried out with practically identical weights of sample and equal quantities of reagents may "agree," but be perfectly worthless because of inherent errors, never really seems to penetrate the mind of many men. The fact that so simple a thing as variation in the quantities taken for analysis is a wise precaution in testing a process is also unperceived. I do not mean to say that most, or possibly all, teachers do not point out these matters, but I do mean to say that many students never get a clear perception of them, and still less of the idea that dependence upon compensation of errors in an analytical procedure is quite insecure unless the factors governing the occurrence of these errors are approximately known. I feel sure that these defects in our teaching would be lessened if we were, in general, to pay less attention to teaching a variety of methods, as such, and more to the careful investigation of a

few, on a scale commensurate with even the limited knowledge which a junior or senior really possesses. This should be done with the purpose of enabling him to criticize his own work, to study it for possible errors, their causes, and, so far as practicable, their amounts. He may then be encouraged to criticize the published work of others, for which, by the way, no end of useful material is at hand. In this connection, it may not be out of place to recommend to chemical analysts, teachers and practitioners an annual perusal of Dr. Hillebrand's address referred to above, in which he deals with the shortcomings of analysts with respect to reagents and manipulative methods, which it has not seemed necessary to attempt to touch upon here.

Finally, just a word regarding the status of the analytical chemist, using this term to denote one with whom analytical chemistry is essentially a vocation. There is, I think, no doubt that this is distinctly unsatisfactory. In the minds of the general public, to be sure, a chemist is essentially an analyst but, in the minds of employers, an analyst is too often an inferior grade of chemist who can be readily displaced by a reasonably intelligent boy, and whom boy's wages should satisfy. Our young men who have been chemically educated almost universally begin their professional careers in the technical field in our analytical laboratory. While we wisely admonish them to fulfil the task at hand in such a way as to earn more than they receive, to more than "make good," in the phrase of the day, we also urge them not to be content with such positions as will permanently restrict them to analytical service. This, too, under existing conditions, is no doubt wise. But it would seem that the time has come when employers should recognize that work entrusted to

boys who, while possibly capable of carrying out routine operations, have no ability to deal with any of the inevitable complications arising from exceptional conditions, or work entrusted even to men who are underpaid and without the encouragement of future adequate recognition, is likely to lack the requisite quality for the attainment of the best possible results. It may not be practicable to create permanently attractive positions for a large number of strong men, but there should be more of these men in the works laboratory than are now found there. Moreover, while a works laboratory is confessedly not a savory neighbor, the chemists should courageously demand that they should not be relegated to some ill-lighted, half-ventilated and dirty corner, as is too often done. This does not mean that quartered-oak desks, glass shelves or expensive trimmings should be asked for, but merely such quarters as will permit self-respecting men, who take pride in their work, to operate under conditions which permit them to render their best service. Some may say that this is an easy suggestion to make on the part of one not immediately associated with the stress of industrial conditions, but one which it is difficult to carry out. This is frankly admitted, but the belief persists that the analytical chemists owe it to themselves to make an effort to secure for themselves and their work a larger measure of recognition such as this suggestion would involve.

If we consider the current prices for chemical analyses, one is prone to think that in one field, at least, competition has had full play. It were, of course, rank heresy in this good city to suggest restraint, and yet it seems full time that something should be done, lest the day might come when the chemist would have to pay the manufacturer for the privilege of ma-

king analyses for him. How can an analytical chemist hope to maintain his professional standing when his charges for individual analyses—even when done in quantity—are such that, unless he is to count his own time as without value (and sometimes even under such an assumption), he can not possibly do reliable work without an actual financial loss? I do not wish to draw any unpleasant or unfair inferences as to which horn of such a dilemma the commercial analytical chemists choose; for the most of them are, no doubt, trying to make the best of a difficult situation. Unfortunately, I have no specific remedy to propose, but it is all too evident that these conditions tend to belittle this branch of our science, to result in a large output of inferior work, and to create a distrust which spreads unduly. It behooves us all to at least do what we can to bring home to those who are to place dependence upon work done at these ruinous prices that, in many instances, they are getting just about what they pay for and no more, and that the service is not such as they owe it to themselves to make possible by more adequate remuneration.

Whether we consider present analytical practise from the view of the scientist or as a vocation, we find much that calls for improvement. What the present situation imperatively demands, then, is a courageous and frank admission that the quality of much of the analytical work, practised or published, is inferior to what might reasonably be attained because much of it is one-sided and ill-considered from a scientific standpoint. Let there be a realization that, while no amount of theorizing can take the place of skilful and accurate work, or of a certain amount of empirical experimentation, the analysts should cease pulling on their own boot-straps and avail

themselves more generally of the aids from other portions of our science to help to lift themselves and their art to the worthy position to which both are entitled. Let the chemical analysts realize that they must take greater pride in their work for its own sake, let them demand a recognition of the dignity claimed for it by Dr. Dudley, and let them give to it the best that is in them, in both activity of mind and skill of hand. This is a duty which is owed to our national reputation, to chemical science, pure and applied, and to our own welfare.

*THE CROCKER LAND EXPEDITION UNDER
THE AUSPICES OF THE AMERICAN
MUSEUM OF NATURAL HISTORY
AND THE AMERICAN GEO-
GRAPHICAL SOCIETY*

THE existence or non-existence of land northwest of Grant Land and the configuration of the polar continental shelf of North America seem to be two of the greatest of the geographical problems still unsolved. There is, in addition, much important geological, geographical, zoological and other scientific work to be done in certain parts of the Arctic regions. Two thoroughly qualified young men have volunteered their services as leaders of an expedition to attack the problems and do the work. Under this combination of circumstances and with the proviso that sufficient funds be provided from outside sources, the American Museum of Natural History and the American Geographical Society have made liberal appropriations in support of the enterprise, and the former institution has taken over its organization and management, feeling that it is well worthy of the backing of the scientific institutions of the country.

The leaders of the expedition are to be George Borup (A.B., Yale, 1907), assistant curator of geology in the American Museum

of Natural History, and Donald B. MacMillan (A.B., 1898; A.M. (Hon.), 1910, Bowdoin). They have become well known to the public, scientific as well as general, through their work under Admiral Peary on his last polar expedition, through Mr. Borup's book, "A Tenderfoot with Peary," and his lectures and through Mr. MacMillan's extensive lecturing throughout the country. They have received Peary's unqualified indorsement for the work in hand. Mr. Borup has been devoting his whole attention during the past two and a half years to studies in the field and at Yale to fit himself thoroughly for scientific geological and geographical exploration. He is a fellow of the Royal Geographical Society (of London) and a member of the New York Academy of Sciences. Mr. MacMillan, since his return from the Peary expedition, has been studying ethnology and practical astronomy at Harvard. In the summer of 1910, he was a member of the Cabot party which was the first to cross central Labrador from the sea to George River, and he spent the summer of 1911 cruising along the coast of Labrador in an eighteen-foot open canoe, studying the Eskimo from Hopedale to Killinek (60° N. Lat.). Mr. MacMillan is a member of the American Geographical Society and the Appalachian Mountain Club.

The object and work of the expedition may, perhaps, be best stated in Mr. Borup's own words:

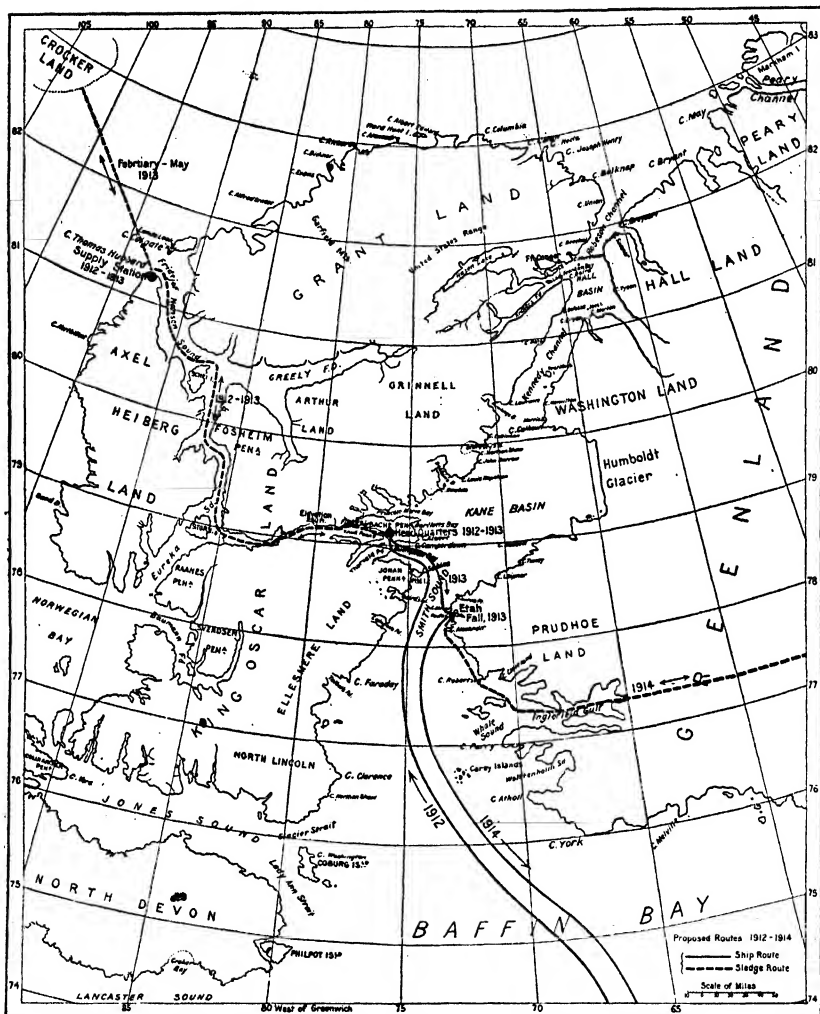

Belief in the existence of a land mass northwest of Grant Land rests on deductions made by Harris and observations made by Peary. Admiral Peary in his book "Nearest the Pole" reports having seen the "faint white summits of a distant land" on 24 June, 1906, from 2,000 feet above sea level on Cape Colgate and again six days later from 1,600 feet altitude on Cape Thomas Hubbard. It was calculated that this land lay about 130 miles out in the polar sea and in 100° W. Long. and 83° N. Lat. To it Peary gave the name Crocker Land. Dr. R. A. Harris in his monograph on "Arctic Tides" (1911) gave his reasons for concluding from a plotting of the cotidal lines of the Arctic regions that a great tract of land, an archipelago or an area of shallow water, trapezoidal in outline and half a million square

(statute) miles in area lies north of eastern Siberia and northern America. He places one corner of his trapezoid northwest of Grant Land and identifies Peary's Crocker Land with it.

The new expedition proposes to make soundings along the line from Cape Thomas Hubbard to Crocker Land, to determine the situation of the continental shelf, to collect samples of the ocean floor and to take temperature observations of the water at various depths and by attaching a small net to the sounding wire, to obtain specimens of oceanic life. These soundings, taken in connection with those made by Admiral Peary between Cape Columbia and the Pole, and by Nansen on the drift of the Fram starting in latitude 78° 50' north, longitude 133° 37' east, north of Siberia, to 85° 57' and thence down the west coast of Spitzbergen, will give a fair idea of the configuration of the floor of the Arctic seas. Tidal observations will be made at Cape Thomas Hubbard and at such points on Crocker Land as are found to be practicable. Such observations are highly desirable as supplementary to the records already secured on the north coast of Greenland and Grant Land by Marvin, MacMillan and Borup in connection with the last Peary expedition. On Crocker Land itself it is proposed to make a topographic map of the coast line and of parts of the interior, and if feasible to map geologically such parts as are visited; but in any case, to note the stage of physiographic development, the formations represented, and to collect specimens of rocks, of fossils and of living plants and animals.

In order to increase the scientific value of this expedition and in order that it may yield definite scientific results in the event of failure to reach Crocker Land, it is proposed to explore and to make detailed scientific observations in Ellesmere Land, Grant Land and Greenland. A part of the north coast of Grant Land will be studied and during one summer or late spring it is proposed to make a trip from Whale Sound (Inglefield Gulf) directly east into the interior of Greenland. By taking this course, the height of the ice cap may be ascertained and observations made of this great ice sheet supplementary to those of Peary, Nansen and Nordenskiöld. Nansen's studies were slightly south of the Arctic circle where the land is not very wide. The two journeys of Peary from Whale Sound to Independence Bay were made relatively near the shore.

After consultation with various scientists as to what classes of work will yield the greatest return, it is proposed to make the following studies:

THE PROPOSED ROUTE OF THE CROCKER LAND EXPEDITION

(a) *Geography*.—The coast lines and interiors will be mapped by plane table, barometer, continuous tracing of valleys, etc.

(b) *General Geology*.—Observations on the geology of Ellesmere Land and Grant Land have been made by the Norwegians under Sverdrup and the English Expedition of 1875-6, but their work was

necessarily of such a preliminary character that very little concerning the age of the formations and the relative abundance and character of the igneous and sedimentary rocks was learned; and nothing concerning the physiographic conditions of these areas was determined. It is proposed therefore to make detailed areal studies of the geology

of these regions and to make rather complete collections wherever possible.

The scattered paleontological data in this region which now are of small value could be made of much greater significance by studies such as are proposed. Along physiographic lines practically nothing has been done and the broad question of cycles of erosion involving possible climatic changes furnishes a fascinating subject of study of far-reaching scientific importance. The structure of these areas as indicating the character and extent of the larger earth movements in the Arctic regions and the original structures of the larger land masses could be determined by such studies as we propose.

(c) *Glaciation*.—It is proposed to make a thorough study of glaciers, glacial motion and the process of erosion by glacial ice caps. The geological importance of ice in molding land forms has been studied in existing glaciers, but the process of land molding under a continuous moving ice cap is not understood and there is here an opportunity for making observations which are significant not only for the present geological era, but also for Permian and Cambrian eras. It is proposed to make a special study of the so-called "glacial fringe" on the shores of the polar sea which to a limited extent resembles the great Ross Barrier of the Antarctic. The land and sea ice meet on the north coast of Grant Land, about five miles off shore. The land ice or "glacial fringe" is not a true glacier, but a combination of glaciers from the land and the heavy ice of the flocks which merge into a sort of piedmont glacier. There are no crevices in the ice surface aside from "tidal cracks," but it is thrown into great swells or waves 30-40 feet high and from a few hundred yards to a mile in length, which run generally normal to the shore. From this fringe come the floe-bergs and many heavy ice floes of the polar seas. This "glacial fringe" forms a unique and interesting feature of glaciation, and a study of its character and effects is of the highest importance to glacialists. In this connection attention has been called to an interesting feature by Colonel Feilden, the naturalist to the English Arctic Expedition of 1875-6, who says: "There is a lot of drift wood knocking about. I got it from off the floes up to 1,000 feet elevation—the interesting question is whether it comes from the Mackenzie or from Siberia? I do hope they will make a most careful investigation of the raised beaches and their contents. Also the birthplace of those mysterious boulders which are strewn along the

shores and to high altitudes in Grand Land and North Greenland."

(d) *Meteorology*.—It is proposed to make continuous barometric and thermometric observations at all points visited and an endeavor will be made by use of box kites to secure data as to temperature and direction of the upper air currents. No work of this sort has been previously done in such high latitudes, and it is probable that interesting data regarding atmospheric circulation will be obtained.

(e) *Tidal Observations*.—As stated before, observations will be made at Cape Thomas Hubbard and at points on Crocker Land. Mr. O. H. Tittman, superintendent of the Coast and Geodetic Survey, in a letter says, "Tidal observations, if carefully made for even a few days at a place, will be appreciated at this office. The localities in which such information appears to be most desired are: Axel Heiberg Island, Greeley Fiord, northwest coast of Grant Land, any undiscovered land to the northwest of Grant Land, the north coast of Greenland at points between Cape Bryant and Cape Morris Jesup. Any soundings which may be taken to the north of known land will be of interest to this office and to geographers generally."

(f) *Ichthyology*.—Hitherto practically no fish have been caught in these waters by any of the previous expeditions except a variety of salmon trout found in fresh water lakes. The fish do not seem to rise to bait.

In Smith Sound and Kane Basin there are great numbers of fish, however, as proved by the innumerable seals found there. Their chief diet is fish. Numerous good-size fish bones were also found in the stomachs of narwhals killed by Peary's last expedition.

By taking nets, trawls, etc., along, fish new to science may be caught and in all events we can prove what kind of fish inhabit these waters.

(g) *Ethnology*.—The Eskimos will be studied, their mode of life, traditions and language. It is planned to take a phonograph and make records of their language, songs, etc.

It is also intended to use the new adaptation of color photography to moving pictures in depicting various phases of animal life. This has never been done in the Arctic. Many very interesting and valuable moving pictures of the life in the north remain to be taken, such as camp life, building igloos, driving dogs, hunting and especially a good walrus fight.

(h) *Ornithology*.—Complete collections of eggs and birds will be made. Photographs of the nest-

ing places and the young will be taken; moving pictures showing the marvellous abundance of bird life, etc., will be secured.

(i) *Mammalogy*.—Specimens of all kinds of animal life will be secured, including bear, foxes, deer, mush oxen, hare, lemmings, walrus, and several kinds of seals. Measurements of narwhals and white seals will be made to supplement those taken by Mr. Roy C. Andrews in the Pacific.

The plan of campaign as laid down by Messrs. Borup and MacMillan is as follows:

Leave Sydney, N. S., by special steamer about 20 July, 1912. Collect whale and walrus meat and dogs on the way northward. Land on the south side of Bache Peninsula (Flagler Bay), Lat. $79^{\circ} 10' N.$, and establish winter quarters. Send the ship home. About the middle of September, begin sledging supplies to Cape Thomas Hubbard, and carry the work on throughout the winter during the moonlight periods. Leave Cape Thomas Hubbard with the return of dawn in February, 1913, and push across the ice to Crocker Land. Leave Crocker Land about 1 May, and return to Cape Thomas Hubbard. Send a messenger to North Star Bay with news of the expedition, to be forwarded by Danish steamer to civilization. Carry on scientific work in Grant Land and along return route to winter quarters on Flagler Bay, arriving there in July, 1913. During the summer, transfer supplies and collections to Etah. In the spring and summer of 1914, make an expedition from Whale Sound (Inglefield Gulf) directly eastward to the summit of the ice-cap of Greenland, at the widest part of that island. Return to New York in the autumn of 1914 by special ship.

The following are some of the principal items of the outfit to be provided: three years' provisions for four or five white men, their helpers and their dogs, much of which, particularly the pemmican, has to be specially prepared and packed; clothing; instruments for all kinds of observations and records; photographic cameras, including those for moving pictures; a power boat for use in Flagler Bay and in crossing to Etah with supplies and collections after the return from

Crocker Land; salary of physician and wages of cook and helpers; a steamship to take the party to Flagler Bay in 1912 and another to go up for it in 1914.

A physician and a zoologist are needed to accompany the party throughout the whole expedition.

It is estimated that not less than fifty thousand dollars (\$50,000) must be provided for the absolute needs of the expedition, in order to enable it to accomplish the valuable results that have been outlined above, in spite of the fact that Messrs. Borup and MacMillan generously serve the expedition without salary during the period of its absence from New York. Subscriptions to the fund are invited. Checks should be made payable to and all correspondence should be addressed to the American Museum of Natural History.

In addition to the support of the institutions already named, subscriptions have already been made or promised by Yale University, Bowdoin College, New York Academy of Sciences, Groton School, Theodore Roosevelt, R. E. Peary, Thomas H. Hubbard, Zenas Crane, Mrs. C. B. Alexander, John E. Thayer and others. There remains to be raised about thirty thousand dollars, and the museum has opened an account, known as the "Crocker Land Expedition Fund," for the purpose of receiving and caring for all subscriptions made to the expedition. Checks to further its purposes should be drawn payable to the American Museum of Natural History and forwarded to that institution. A list of subscribers will be published later and will be included in the final report.

The honorary committee on the Crocker Land Expedition consists of Henry Fairfield Osborn, president, American Museum of Natural History; Chandler Robbins, chairman of the council, American Geographical Society; Thomas H. Hubbard, president, Peary Arctic Club.

The committee in charge comprises E. O. Hovey, American Museum of Natural History; H. L. Bridgman, Peary Arctic Club.

All correspondence regarding the expedition should be addressed to Dr. Hovey.

GEORGE JARVIS BRUSH

GEORGE JARVIS BRUSH, LL.D., professor of mineralogy, emeritus in Yale University, died at his home in New Haven on February sixth in his eighty-first year. He was the last survivor of the first class to graduate from the Scientific School and the last member of a small group of distinguished men, who in the early days of the school devoted their lives to its service. With him passes a scientist who did much for the development of the science of mineralogy in this country and one who did even more for the general cause of scientific study and research.

He was born in the city of Brooklyn, December 15, 1831. An illness when a boy forced him to spend a year in the country and from this arose an interest in agricultural problems which later led him to Yale to take the newly established course in agricultural chemistry taught at that time by Professor J. P. Norton. In this way he became deeply interested successively in the subjects of chemistry, metallurgy and mineralogy. He entered Yale in 1848, leaving in 1850 to become an assistant in chemistry to Professor Benjamin Silliman, Jr., at Louisville. He received, however, in 1852 the degree of Bachelor of Philosophy with his class at Yale. In the same year he became an assistant in chemistry at the University of Virginia. It was here that he did his first important work in mineralogy in collaboration with Professor J. Lawrence Smith. Together they published a series of articles entitled "Reexamination of American Minerals," in which many new analyses were given and many points clarified which had been obscure in the early descriptions of American minerals. In 1853 Brush went abroad and spent two years of study in the laboratories at Munich and Freiburg. He returned to New Haven in 1856 as professor of metallurgy, which title he retained until 1864, when it was changed to professor of metallurgy and mineralogy. In 1871 the title was again changed to professor of mineralogy and this was retained until his death, the word *emeritus* being added in 1898 when he retired from active duties. He was deeply in-

terested in the development of the new scientific school in which he taught and was largely instrumental in its incorporation as the Sheffield Scientific School in 1861. He became the first director of the institution in 1872 and retained that office until his resignation in 1898. The earlier years of this period were critical ones, not only for the Sheffield Scientific School, but for the general cause of scientific education in this country. It is to be remembered that the public sentiment toward science was very different then from what it is to-day. At that time men like Professor Brush were especially needed who, with courage and far-sighted ideals, could strive against and gradually overcome the general distrust and disfavor with which scientific education was considered. In the scientific school he gathered a faculty of notable men about him and through his enthusiasm and faith inspired them with a devotion and unity of purpose which has had few parallels.

Much of his power lay in his ability to successfully organize and direct. That he had a keen business sense is shown in the material advancement of the school under his leadership and also in the fact that his services were always in demand by various public business organizations as a director and officer.

In his younger days, before his administrative duties became too heavy, Brush did considerable investigation in mineralogy, as the appended bibliography will show. He was, furthermore, always an inspiration to other workers in that field. It was through his enthusiasm and interest that the remarkable mineral locality at Branchville, Connecticut, was thoroughly explored. The results of these investigations were published in a series of papers by him in collaboration with Professor E. S. Dana. The work also involved a series of chemical analyses by S. L. Penfield and H. L. Wells, who were at that time graduate students in the Scientific School. Penfield later became assistant to Brush and finally succeeded him as acting professor of mineralogy

when administration duties compelled the latter to relinquish his teaching.

Brush also did much important work along the lines of the systematization of mineralogy. He wrote the eighth, ninth and tenth supplements to the 4th edition of Dana's "System of Mineralogy." He assisted in the preparation of the 5th edition of that book and wrote its first appendix. In 1874 he published his "Determinative Mineralogy and Blowpipe Analysis," a book which passed through fourteen editions until 1898 when it was revised by S. L. Penfield.

He commenced to assemble a mineral collection when a boy of fifteen years of age. His first specimen, which is still preserved, was collected at Salisbury, Connecticut, in 1846. This was the nucleus of what has since grown to be a collection of more than fifteen thousand specimens. The Brush Mineral Collection, as it is called, is in many ways unique. The idea that its founder always had in mind was to make it a collection for study rather than one for exhibition. It does not include, therefore, as many large or striking specimens as some of our public collections, but is, on the other hand, particularly rich in representative and type material. It is the repository of most of the minerals which have been the subject of investigation at Yale during the last forty years. From the viewpoint of the student of mineralogy, therefore, it ranks high among the mineral collections of the world. Together with a large mineralogical library it was given to the Sheffield Scientific School in 1904 accompanied with an endowment fund to provide for its future maintenance. The Brush Mineral Collection will therefore always remain one of the treasures of Yale and form a notable monument to its founder.

Professor Brush was elected a member of the National Academy of Sciences in 1868 and received the degree of Doctor of Laws from Harvard University in 1886. He was president of the American Association for the Advancement of Science in 1880. He was an honorary member of the Mineralogical Society of England, was a foreign member of

the Geological Society of London, of the Geological Society of Edinburgh, of the Royal Bavarian Academy of Sciences of Munich and various other learned societies, both at home and abroad.

It is seldom that we have a man of such wide influence along so many different lines who can combine, as he did, the activities of the scientific investigator, the duties of the organizer and the services of the public-spirited citizen. His character, combining, as it did, the scientist's demand for truth and accuracy with the kindly spirit of the broad-minded gentleman, was an inspiration to all who knew him. His optimism, his generous nature, and his readiness to serve were qualities that endeared him to his colleagues and to the many students with whom he came in personal contact.

WILLIAM E. FORD¹

THE RAINEY AFRICAN EXPEDITION

MR. EDMUND HELLER, who represented the Smithsonian Institution on Mr. Paul J. Rainey's African Expedition, writes from Kisumu, British East Africa, January 26, 1912, that the expedition has been completed but that a delay has been caused in the shipment of specimens collected by Mr. Rainey and himself, due to the lack of porters, transportation facilities, etc. The collection, which arrived at Nairobi two weeks prior to the date of his letter, has been packed and forwarded by him to the Smithsonian Institution. While waiting for a steamer from Mombasa, Mr. Heller put in a couple of months in making collections at various stations of the Uganda Railroad, including some districts not touched by the Smithsonian Expedition under Colonel Roosevelt, and also about Lake Victoria Nyanza. By this means he has been able to add many species to the Smithsonian collection, as well as to finish a really complete survey of the mammals of British East Africa. He will probably spend a few weeks at the British Museum, and at the Berlin Museum, in comparing and identifying some of the specimens collected. The trip was most satisfactory in every way, and Mr. Heller estimates that the collection will rival that made by the Smithsonian African Expedition under Mr. Roosevelt in 1909 and 1910. In all there are about 700 large mammal skins in salt, 4,000 small mammal skins, and a large number of

¹ Assistant professor of mineralogy in the Sheffield Scientific School of Yale University and curator of the Brush Mineral Collection.

birds and reptiles, most of them coming from regions not visited by the previous expedition, while some are from remote localities never before visited by naturalists. After the completion of his studies in Europe, Mr. Heller will return to Washington, to complete his report on the mammals of British East Africa.

THE PACIFIC ASSOCIATION OF SCIENTIFIC SOCIETIES

THE second annual meeting of the Pacific Association of Scientific Societies will be held at Stanford University on April 4, 5, 6, 1912. Sessions will be held this year on one or more of the above days by the following eight societies:

The Technical Society of the Pacific Coast.

The Cordilleran Section of the Geological Society of America.

The Seismological Society of America.

Pacific Coast Branch of the American Historical Association.

The Pacific Slope Association of Economic Entomologists.

Pacific Paleontological Society.

The Biological Society of the Pacific.

The California Section of the American Chemical Society.

There will also meet with the Association the LeConte Club and the Mathematical Society of the Pacific Coast.

Friday evening will be used generally for dinners and banquets, and on Saturday evening will be held the general session of the association. President Jordan will give the address of welcome, and among the readers of papers will be Professor A. C. Lawson, University of California, Professor George Hemphill, Stanford University, and Director W. W. Campbell, of the Lick Observatory.

The Pacific Association of Scientific Societies was organized in 1910 "to promote cooperation among the constituent societies." It is to make possible the getting together of a number of smaller isolated societies annually at the same time and place. The administrative machinery of the association is an Executive Committee composed of the presidents and secretaries, or their representatives, of the constituent societies. The principal business of this committee is to suggest

time and place of meeting and make arrangements for such meetings.

Nine Coast Societies became members the first year:

The Technical Society of the Pacific coast.

The Cordilleran Section of the Geological Society of America.

The Seismological Society of America.

Pacific Coast Branch of the American Historical Association.

The Pacific Slope Association of Economic Entomologists.

Pacific Coast Paleontological Society.

The Philological Society of the Pacific Coast.

The Cooper Ornithological Club.

California Academy of Sciences.

The second year two more societies became members:

The Biological Society of the Pacific.

The California Section of the American Chemical Society.

The present officers of the association are:

Chairman of the Executive Committee, Mr. Otto von Geldern.

Vice-chairman, Professor George D. Louderback.

Secretary-treasurer, Professor J. N. Bowman.

The first meeting of the association was held at the University of California on March 31-April 1, 1911. The different societies accepting the suggested time and place, held their sessions on the campus; on Saturday evening the general session of the association convened in California Hall. At this session addresses and papers were given by Chairman Otto von Geldern, President Benjamin Ide Wheeler, President David Starr Jordan, Professor Vernon Kellogg, Mr. George W. Dickie and Professor Bernard Moses. The same general plan will be followed this year at the second annual meeting at Stanford University. The work of the various secretaries is greatly facilitated by the committee on arrangements appointed by President Jordan and composed of Professors Townley, Heath and Burlingame.

SCIENTIFIC NOTES AND NEWS

MR. SAMUEL HENSHAW has been appointed director of the Museum of Comparative Zoology of Harvard University.

PROFESSOR CHARLES JAMES, of New Hampshire College, has been awarded the Nichols medal of the American Chemical Society.

DR. A. E. ORTMANN, curator of invertebrate zoology, Carnegie Museum, and professor of physical geography, University of Pittsburgh, has been elected a member of the *Halle Académie of Sciences*.

MR. GUGLIELMO MARCONI has been appointed a life senator by the Italian government.

THE following fifteen candidates have been selected by the council of the Royal Society to be recommended for election into the society: Professor J. O. Arnold, Professor C. G. Barkla, Mr. L. Cockayne, Mr. A. L. Dixon, Sir T. L. Heath, Dr. H. O. Jones, Professor T. R. Lyle, Dr. W. McDougall, Mr. R. Messel, Professor B. Moore, Mr. E. Nettleship, Mr. R. Newstead, Vice-Admiral Sir H. J. Oram, Dr. G. T. Prior and Mr. R. C. Punnett.

THE following have been appointed members of the American Commission on Inorganic Nomenclature of Chemistry, to co-operate with similar national bodies of other countries: Jas. Lewis Howe, of Washington and Lee University, chairman; P. E. Brown-ing, of Yale; E. C. Franklin, of the Hygienic Laboratory, Washington; A. M. Patterson, Xenia, O.; Chas. H. Herty, of the University of North Carolina; Owen Shinn, of the University of Pennsylvania, and Adolf Law Voge, of the Library of Congress.

At its last meeting the Rumford committee of the American Academy of Arts and Sciences granted the sum of \$250 additional to a former appropriation to Professor Gilbert N. Lewis, of the Massachusetts Institute of Technology, in aid of his research upon the free energy changes in chemical reactions.

RECENT appointments to the research staff of the Otho S. A. Sprague Memorial Institute, Chicago, are Dr. Lydia M. DeWitt, formerly of the department of anatomy at the University of Michigan, and more recently of the health department of the city of St. Louis, and Dr. Samuel Amberg, of the department of pediatrics at Johns Hopkins Medical School.

DR. R. RAMSAY WRIGHT, vice-president of the University of Toronto and dean of the faculty of arts, will retire from active service on September 30. He has filled the chair of biology for the last thirty-eight years.

PROFESSOR EDWARD HICKING JACKSON, professor of orthopedic surgery at the Harvard Medical School, and Professor James Jackson Putnam, professor of diseases of the nervous system, have retired from active service and will be given the title of professor emeritus.

MR. N. E. DORSEY, Ph.D. (Hopkins, 1897), associate physicist in the U. S. Bureau of Standards, has been appointed research associate in the department of terrestrial magnetism of the Carnegie Institution of Washington.

DR. GEORGE A. HULETT, professor of physical chemistry, at Princeton University, has received leave of absence for the academic year 1912-13, in order that he may accept, for the year, the post of chief chemist in the U. S. Bureau of Mines.

MISS MARGARET HARWOOD, of the Harvard College Observatory, has been appointed to the astronomical fellowship of the Nantucket Maria Mitchell Association.

PROFESSOR W. BALDWIN SPENCER, F.R.S., has been appointed protector of the aborigines in the northern territory of Australia.

DR. SCHLAGINHAUFER has been chosen as the successor of Dr. R. Martin at the head of the Anthropological Institute, Zurich.

DR. W. J. HOLLAND, director of the Carnegie Institute, Pittsburgh, has been appointed by the Entomological Society of London to represent it at the centenary of the Academy of Natural Sciences of Philadelphia.

DR. A. HRDLICKA has been designated as the representative of the Smithsonian Institution at the eighteenth International Congress of Americanists, to be held at London from May 27 to June 1, 1912. Dr. Hrdlicka has also been accredited as a delegate to the congress on the part of the United States.

DR. C. H. EIGENMANN, curator of ichthyology at the Carnegie Museum, reports himself

as highly successful in his exploration of the Rio Magdalena and the Rio Atrato, in which he is making large collections of fishes for the museum.

MRS. T. D. A. COCKERELL has just returned from Guatemala, where she collected both in the mountains and in the tropical lowlands, and obtained a large collection of bees and other insects, as well as some reptiles, fishes, plants, etc.

DR. LOUISE B. WALLACE, associate professor of zoology at Mt. Holyoke College, has been granted two years leave of absence to take charge of the biological department in the American College for Girls in Constantinople.

DR. MAX BORN, of the University of Göttingen, is to lecture on relativity during the summer quarter at the University of Chicago. The course is to continue throughout the entire quarter.

PRESIDENT F. P. VENABLE, of the University of North Carolina, lectured before the Chemical Society of Washington and Lee University on March 1, on "The Value of Chemical Research."

DR. M. P. RAVENEL, of the department of bacteriology of the University of Wisconsin, is delivering a series of six lectures before the Milwaukee Medical Society on "Studies in Immunity, Vaccine and Serum Therapy."

PROFESSOR LAFAYETTE B. MENDEL, of the Sheffield Scientific School of Yale University, lectured before the students of Mt. Holyoke College on March 2, on "Changing Views on Nutrition."

At a meeting of the Geographical Society of Chicago on March 8, a lecture was given by Mr. Alfred H. Brooks of the U. S. Geological Survey, the title of the lecture being "Geography of Alaska."

PROFESSOR J. G. D. MACK, the exchange lecturer from the University of Wisconsin, gave two lectures before the students and faculty of the College of Engineering of the University of Illinois on February 29. One lecture was on the engineering features of the Wisconsin Tax and Public Utilities Com-

missions. Professor Mack is a member of the engineering staff of these commissions. The second lecture was on some features of ancient engineering work and their relations to present-day practise, and was, in part, an appeal to engineering students to study the history of engineering as well as current practise.

DR. LYNDY JONES, associate professor of animal ecology in Oberlin College, lectured recently before the undergraduates in Spear Laboratory upon "The Winter Birds of Ohio." From now on to the end of the college year Dr. Jones is offering a seminar in practical field work in ornithology which has been elected by about ten advanced students.

DR. JOHN BERNHARDT SMITH, state entomologist of New Jersey and professor of entomology at Rutgers College, eminent for his contributions to entomology, died on March 12, aged fifty-four years.

PROFESSOR MASON BLANCHARD THOMAS, B.S. Cornell '90, Ph.D. '07, professor of botany at Wabash college since 1891, and dean of the faculty since 1907, died at Crawfordsville, Ind., on March 6, aged forty-six years.

DR. SAMUEL AUGHEY died in Spokane, Washington, on February 3, 1912, at the age of eighty-one. He was a graduate of Pennsylvania College, Gettysburg, and of the Theological Seminary of the same place. After some years in the ministry, during which time he moved with his family to Nebraska and soon became noted as an enthusiastic naturalist, he was elected to the chair of natural science in the newly established State University of Nebraska, where he remained for thirteen years. On severing his connection with the university, he devoted himself more especially to geology and the practical work of the mining expert. Among his publications are "A Catalogue of the Flora of Nebraska" (1875); "Physical Geography and Geology of Nebraska" (1880); "Geological Report on the Wyoming Oil Basins" (1881), etc.

PROFESSOR OSBORNE REYNOLDS, the distinguished engineer and physicist, for many years professor at the Owens College, died on February 21, aged seventy years.

SIR JOHN G. N. ALLEYNE, Bt., known as an authority in engineering and for his interest in iron and steel research, has died in his ninety-second year.

DR. A. H. YOUNG, emeritus professor of anatomy in the University of Manchester, died on February 22.

PROFESSOR RICHARD ANDRÉE, of Leipzig, known for his work in geography and ethnography, has died at the age of seventy-seven years.

THERE is existing a vacancy in the position of chief engineer, Indian Irrigation Service, at a salary of \$4,000 per annum. The requirements of the position are technical in their nature, the work having to do with the planning and construction of all the irrigation work under the control of the Office of Indian Affairs. The government is endeavoring to find the best man available for this work, and has no particular individual in view. The qualifications and fitness for this position, based upon education, training and experience in the design and construction of engineering works, will be determined by a board of experienced engineers. Qualified persons who are interested in this position are invited to communicate with the U. S. Civil Service Commission, Washington, D. C. The commission also announces a vacancy in the position of research bacteriologist in the biological laboratory of the Bureau of Science, Manila, Philippine Islands, at a salary of \$2,500 a year. This position is for a research bacteriologist with clinical experience, and applicants must be graduates in medicine; in addition they must show that they have specialized extensively in bacteriology and are capable of doing original research work. The work comprises investigations in tropical medicine in conjunction with the chief of the biological laboratory, who is also professor of tropical medicine in the College of Medicine and Surgery. The clinical material of the Philippine General Hospital and the hospital of the government prison will be available for study in connection with bacteriological investigation. It is stated by the Bureau of Science that opportunities exist for promotion

to higher places as vacancies occur, and at present there are six positions in this laboratory above the one in question, at salaries ranging from \$2,500 to \$5,000 a year. The library of the Bureau of Science and the equipment are of the very best and strictly modern, so that this position offers a unique opportunity for a young man who is ambitious to do research work.

THE treasurer of Columbia University has reported to the trustees that he had received about \$1,550,000 from the executors of the estate of the late George Crocker. Accordingly, the work of cancer research, for which Mr. Crocker gave this sum as an endowment, will begin at once. The research fund will be intrusted for administration to a board of managers, to consist of Mr. Rives, Dr. Cheesman and President Butler from the trustees, and Dean Lambert, Professors Janeway and MacCallum, of the medical faculty, together with a director of Cancer Research to be appointed.

THE Scripps Institution for Biological Research at San Diego is about to be made a part of the University of California. It was built up through the aid of Miss Ellen B. Scripps and Mr. E. W. Scripps. Control, heretofore in the hands of the San Diego Marine Biological Association, will be delegated by the University to Miss Ellen B. Scripps, Mr. E. W. Scripps, President Benjamin Ide Wheeler, of the university, and Dr. William E. Ritter, professor of zoology and director of the Scripps institution.

UNIVERSITY AND EDUCATIONAL NEWS

THE Brown University endowment fund has received a gift of \$10,000 from Mr. J. B. F. Herreshoff, an alumnus, vice-president of the Nichols Chemical Company of New York. This makes \$762,417 towards the million dollar fund.

THE budget of Columbia University calls for the expenditure of \$3,159,730.28 during the year beginning July 1. It is estimated that the income for the same period will fall short of meeting the expenditure by \$132,000, de-

spite the fact that the income on a large part of the John Stewart Kennedy bequest is now available. The largest single item of expense is for educational administration and instruction, \$2,180,402. Next to this come appropriations for buildings and grounds, the sum being \$332,593. The interest on the corporate debt will amount to \$114,870, while \$100,000 will be set aside and added to the redemption fund. Stated according to the various corporations of the university, the budget is divided as follows: Columbia College, \$2,101,512.28; Barnard College, \$217,725; Teachers College, \$803,470; College of Pharmacy, \$37,020.

A SPECIAL meeting of the Oberlin trustees was held on March 13 to consider plans presented by Mr. Cass Gilbert, of New York City, regarding the location of the new buildings made possible by the completion of the half million endowment. Mr. Gilbert's plans include a science quadrangle at the northwest end of the campus. Here it is proposed to erect four large laboratories to accommodate the departments of physics, zoology, geology and botany. Part of the equipment of the botanical building will be a series of greenhouses. The department of chemistry is already comfortably housed in a separate building, Severance Chemical Laboratory.

DR. HORACE DAVID ARNOLD has been appointed dean of the Harvard Medical School to fill the place made vacant by the resignation of Dr. Henry A. Christian.

DR. TALCOTT WILLIAMS, associate editor of the *Philadelphia Press*, has been appointed director of the School of Journalism of Columbia University, founded by Mr. Pullitzer. Professor John W. Cunliffe, now head of the department of English of the University of Wisconsin, is the associate director of the school.

DR. DOUGLAS W. JOHNSON, assistant professor of physiography in Harvard University, has been appointed associate professor of physiography at Columbia University.

DR. J. E. WALLACE WALLIN has accepted a

call from the University of Pittsburgh to organize a department of clinical psychology.

DR. MURRAY S. WILDMAN, A.B. (Earlham, '93), Ph.D. (Chicago, 04), now professor of economics and commerce in Northwestern University, has been appointed professor of economics in the Leland Stanford Jr. University, to fill the vacancy caused by the resignation of Professor Alvin S. Johnson, who goes to Cornell University at the close of the present academic year.

DR. H. W. FOOTE has been promoted to be professor of physical chemistry in the Sheffield Scientific School of Yale University.

DISCUSSION AND CORRESPONDENCE

THE CORN SNAKE IN NEW JERSEY

WHILE at Chatsworth, Burlington County, N. J., on July 11, 1911, I called on Mr. George Bozarth, the hotelkeeper, who buys up local snakes, excepting rattlesnakes, of which there are still a few in that part of the pine barrens. Noting that the box where he kept his reptiles contained only pine and king snakes, I inquired if he had any other species. He replied that he had but the day before thrown out a corn snake, which had died. He added he had but few of that kind brought in, but that they were to be occasionally met with in the vicinity. After some search we found the reptile, which was still in a good state of preservation and which I showed to various people living near Jones's Mill, a short distance to the east of Chatsworth, eliciting the information that the corn snake occurred in the vicinity, but was far rarer than the pine snake.

My specimen has the dorsal rows of scales weakly keeled, as described by Cope, and the color pattern also fits the description admirably. It has also been compared with living specimens in the New York Zoological Park. It is thirty-four inches in length.

In the "Amphibians and Reptiles of New Jersey," by Henry W. Fowler, published in the Annual Report of the New Jersey State Museum for 1906, I do not find the corn snake, *Coluber guttatus* Linn., recorded, nor

is it mentioned in the supplements that have since been published. Cope says:

This species ranges the Austroriparian region east of the Mississippi River, and the Carolinian district of the Eastern, not, however, entering New Jersey.

It appears, however, from the above record that there is at least one colony of corn snakes to be found in the pine barrens of New Jersey.

WM. T. DAVIS

STATEN ISLAND, N. Y.

FUNDULUS AND FRESH WATER

THE notes which have recently appeared in SCIENCE in regard to the capacity of salt-water minnows to survive being transferred to fresh water, remind me that the experiment has been, and I suppose still is tried, on what I may call a commercial scale, in south-eastern Massachusetts. "Mummichugs" (*Fundulus* spp.) are the favorite, practically the only, bait for winter pickerel fishing through the ice, and it was a very common practise to catch them in large quantities in salt water in the late fall, and keep them in running fresh water all winter.

When I lived on a farm in Middleboro, Mass., in 1892-96, one of my neighbors always had them for sale, during the pickerel season. He used to catch them in Buzzard's Bay, some fifteen miles away, and kept them in a perforated box, placed in a running brook. I have more than once bought "Mummichugs" from him, and, if my memory does not play me false, have kept them alive for some time in a boxed-in spring on my farm. They must have been in confinement at least a month, but seemed in perfect health and were very vigorous and active. Had there been any serious mortality among them, it certainly would not have paid him to keep them for sale.

As a matter of fact, I believe that live *Fundulus* for bait are to be had regularly in the Boston fish markets every winter, and my impression is that they are kept in tanks fed with ordinary tap water.

I may add that I use a good many "Mum-

michugs" for live bait every summer, and find them remarkably tenacious of life. If covered with wet seaweed, they keep lively for several hours even in hot weather.

BOSTON, MASS.

SCIENTIFIC BOOKS

Vergleichende Physiologie. By AUGUST PÜTTER. Jena, G. Fischer. 1911. Pp. 721; illustrations 174.

The title of this book, "Comparative Physiology," is misleading and the author, who is a professor at Bonn, endeavors to justify it in his introduction. The task of general physiology, he says, is the investigation of the general problems of life; comparative physiology is a method, the object of which is to enable one to comprehend the fundamental physiological similarities of organisms. The book therefore does not rehearse the physiological differences of species or larger groups, but deals with general physiology. "Allgemeine Physiologie" would have been a better title, had it not conflicted with that of his master Verworn's book. The facts are drawn chiefly from invertebrate animals and plants, a helpful list of which, with both scientific and common names, family, order and class, is given at the end. There are ten chapters, most of them long, rambling, and clumsily subdivided. In one case, the same heading is used for two distinct and separate sections. The index is wretchedly incomplete. Notwithstanding these technical defects, the book is a valuable addition to the growing literature of general physiology. It is very modern: most of its references to literature belong to the last decade; but again the great bulk of American physiology is unnoticed.

The morphological substratum of vital processes is passed over very briefly, only a few facts being presented regarding colloids, adsorption compounds, membranes, alveolar structure, and the chemical constituents of living substance. The term "living substance" is an abstraction; several kinds of

living substance are always combined to form a living system. The simplest living system is the cell, which comprises at least three structural substances, plasm, nucleus and membrane. More than one quarter of the text is devoted to metabolism. Here the author's tendency to avoid the conventional, which is evident throughout the book, is at once illustrated by his sharp separation between "Baustoffwechsel," and "Betriebsstoffwechsel," comprising respectively the metabolic processes involved in the building of body substance and those not so involved. The actions on metabolism of such conditions as temperature, light, altered concentration of food stuffs, hunger, absence of oxygen, and accumulated metabolic products are discussed. In a subsequent chapter on nutrition, the author presents with experimental evidence his theory that many aquatic animals are nourished by organic food dissolved in the surrounding water, and maintains that this has now been proved for many coelenterates, entomostracans, tunicates and some fishes. Resorption is discussed from the modern standpoint. The chapter headed "Exchange of Matter," allows a modern treatment of such general physiological topics as the resorption of oxygen and of solid substances in solution, the exchange of water, excretion, secretion, and the distribution of matter in plants and animals. Here many of the facts and principles of respiration, excretion and circulation are introduced, but there is no attempt to treat these topics along the conventional lines of vertebrate physiology. The chapter on the conditions of life ends with a discussion of the problem of the duration of life, with references to the work of Calkins and of Woodruff.

A separate chapter is devoted to transformations of energy and includes mechanical and chemical energy, light, electricity and heat. The author accepts Hürthle's ideas regarding the structure of muscle and, following Koltzoff's general conception of the relations of plasm and fibrillæ, believes the fibrillar rods to be elastic bodies which are under tension when the muscle is at rest. In contraction

there occurs a sudden change in the osmotic relations of the sarcoplasm and the isotropic disk, either a decrease of osmotic pressure in the former, or an increase in the latter; the membrane between the two undergoes an increase in permeability; water passes from the sarcoplasm to the isotropic substance; and the elastic tension of the fibrillar rods is released. Fröhlich's view of tonus is followed, according to which tonus represents a slight tendency to continuous contraction of a relatively small number of the fibers of a highly irritable muscle, resulting from the action of very feeble stimuli coming from nerve tissue. Contracture, on the other hand, is a purely muscular condition present in fatigued, narcotized and asphyxiated muscle, and represents a partial inability of all the muscle fibers to extend their elastic elements. The cilium, like the muscle fiber, contains an elastic and a plasmic constituent, and the interactions of the two result in the ciliary movement. Amœboid movement is probably similar in principle, the elastic element perhaps being represented by the superficial layer of the amœboid cell. The increase in the permeability of the plasmic membrane that occurs during contraction is associated with a reversible coagulation resulting from the action of the stimulus on metabolic processes.

Under the general heading of responses to stimuli the author discusses many of the current topics of general physiology, such as irritability, the law of the threshold of stimulation, the all-or-nothing law, conduction, the latent period, fatigue, the treppe, the refractory period, spontaneity, taxis and tropism, tonus, rhythm and the question of its myogenic or neurogenic origin, and the relation between irritability and metabolism. In many of these the author shows himself to be under the influence of the school of general physiology that is headed by Verworn. Sense organs are treated in a broad manner, attention being given not only to the various special senses of animals, but to analogous mechanisms in plants, such as the ocelli in leaves and the static relations of starch grains. In discussing the possibility of hearing by fishes a

warning is pronounced against a too wide generalization of the fact that a few species of fishes have been proved to react to tones. Sections are devoted to the chemical senses, with special reference to investigations on invertebrates, and to unknown senses.

It is in the treatment of the nervous system that the author breaks farthest away from conventional paths and takes a partisan stand on debatable ground. The neurone theory is not accepted, but throughout the whole nervous system there is a complete continuity of living substance. Neurofibrillæ are merely the skeleton of the nerve cell; the neuroplasm is the conducting part. Poisons have revealed the presence of at least six different kinds of living substance in the nervous system: the irritability of the end-organs of cross-striated muscle, of the end-organs of glands, the cardiac branches of the vagus nerve and of smooth muscle, and of sympathetic ganglion cells being depressed by curare, atropin and nicotine, respectively; the irritability of motor cells, intercalated cells and sense cells being augmented respectively by phenol, by strychnine and by neither phenol nor strychnine. Motor differ from non-motor cells in possessing less fatiguability, less need of oxygen and less sensitiveness toward narcotics. The central type of nerve substance is sharply differentiated from the peripheral type by various characteristics, such as its power of summation, certain peculiarities of its conductivity, its greater tendency toward fatigue and its greater need of oxygen—all of these differences, however, being quantitative and capable of being overcome by experimental devices. The author discusses the "adequate," or normal, stimuli for the successive nerve elements that partake in a reflex action, and raises the question whether internal secretions may not constitute the adequate stimuli for the cells of the sympathetic system. Reflex actions are discussed and numerous examples are cited to illustrate their principles. Brief sections are devoted to tonus, to inhibition, as to the theory of which no definite stand is taken, and to instincts; and the chapter ends with a dis-

cussion of the motor reactions of animals, which cites Yerkes's work. The final chapter deals with a comparison of organisms.

FREDERIC S. LEE

COLUMBIA UNIVERSITY

Star Lore of All Ages. By WILLIAM TYLER OLCOTT. G. P. Putnam's Sons. 1911. Pp. xxii + 453, illustrated.

The star groups or constellations, so fantastically figured in the ancient maps, are of unknown antiquity; they are found described in the earliest writers of the Greeks, and upon the tablets of Babylon. Around each group has collected a vast number of traditions, myths and legends; and these traditions Mr. Olcott has traced to their sources, the legends and myths he has collated, and has put all into a very readable form. The book is most attractively printed and illustrated and should be of interest to all who like to watch the stars.

CHARLES LANE POOR

COLUMBIA UNIVERSITY

SCIENTIFIC JOURNALS AND ARTICLES

THE opening (January) number of volume 13 of the *Transactions of the American Mathematical Society* contains the following papers:

E. Landau: "Ueber eine idealtheoretische Funktion."

R. G. D. Richardson: "Theorems of oscillation for two linear differential equations of the second order with two parameters."

E. J. Miles: "The absolute minimum of a definite integral in a special field."

E. G. Bill: "An existence theorem for a problem of the calculus of variations in space."

L. E. Dickson: "Linear algebras."

R. L. Moore: "A note concerning Veblen's axioms for geometry."

Joseph Lipke: "Natural families of curves in a general curved space of n dimensions."

F. R. Moulton: "A class of periodic orbits of superior planets."

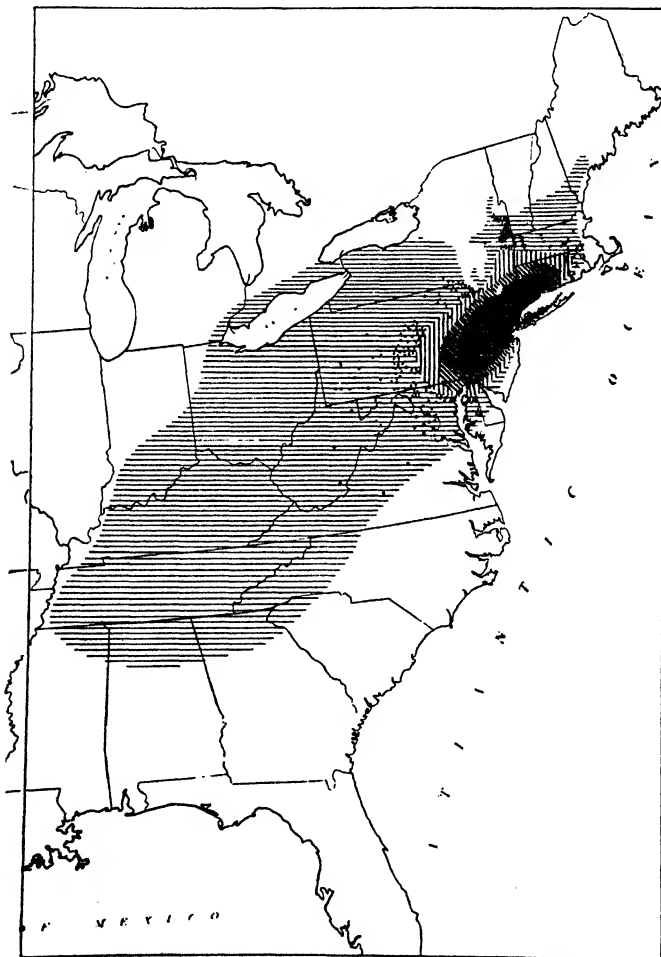

O. D. Kellogg: "Harmonic functions and Green's integral."

THE February number (volume 18, number 5) of the *Bulletin of the American Mathe-*

matical Society contains: Reports of the eighteenth annual meeting of the society and of the fifth regular meeting of the South-western Section, by the secretaries; "Series of Laplace's functions," by B. H. Camp; "On a new mixed problem of the partial differential equation of telegraphy," by A. G. Webster; "Non-Euclidean geometry" (review of Sommerville's "Bibliography of Non-Euclidean

Geometry"), by R. C. Archibald; "Notes"; "New Publications."

THE first number of a new architectural journal, entitled the *Architectural Quarterly of Harvard University*, will be published this month. The purpose of the periodical is to present in easily accessible form important work by students, special lectures delivered in the school, and contributions by members of

THE DISTRIBUTION OF THE CHESTNUT BARK DISEASE

the teaching staff and graduates. The principal article in the first number will be an illustrated paper on "Architectural Acoustics" by Professor W. C. Sabine, with a practical discussion of a number of recent theaters, lecture halls and churches. The number will also contain several drawings of important examples of European architecture and an essay on "The Mediæval Town Halls of Italy" by H. E. Warren, S.M. in Architecture, 1905. Early numbers of the *Quarterly* will contain examples of recent work in architectural design by students of the school, a paper on professional practise, the substance of three lectures recently delivered before the school by Mr. Cass Gilbert, of New York (lately president of the American Institute of Architects), and papers on the teaching of architectural design by Professor Duquesne, on the study of architectural history in its relation to the professional study of architecture by Professor H. L. Warren, and further papers on acoustics by Professor Sabine.

THE PRESENT KNOWN DISTRIBUTION OF THE CHESTNUT BARK DISEASE.

THE writers published in Farmers' Bulletin 487, page 6 (issued October 28, 1911), a map showing the distribution of the chestnut bark disease as known in June, 1911. Since that time the disease has spread considerably, also our detailed knowledge of its distribution has increased. In the map here published, thin horizontal lines show the general distribution of uninfected *Castanea dentata*. Thick lines variously arranged in concentric bands indicate general regions of gradually increasing infection which culminate in the region of practically complete destruction of the tree about New York City. Black dots represent the location of advance infections, many of which have already been eradicated. The writers are under obligations to Dr. Perley Spaulding, Professor A. H. Graves, Mr. I. O. Williams, Mr. S. B. Detwiler and the members and employees of the Chestnut Tree Blight Commission of Pennsylvania, Mr. W. H. Rankin, Mr. J. F. O'Byrne, Mr. F. W. Bealey, Dr. Ernest S. Reynolds, Mr. H. G.

MacMillan, Professor H. R. Fulton and Mr. A. B. Brooks, for much of the data used in compiling this map.

WASHINGTON, D. C., February 1, 1912

SPECIAL ARTICLES

SENILITY IN MERISTEMATIC TISSUE

MERISTEMATIC tissue in perennial plants is commonly believed to retain its embryonic condition unchanged. Senility is considered to occur only in specialized cells. A twig cut from a mature tree and planted or grafted is said to produce a new tree as youthful in its protoplasmic vigor as a seedling. While these are almost the unanimous opinions of the botanists, it is interesting to note that many fruit growers and gardeners have always held that vegetatively propagated plants tended to run out, as if through senility.

In order to determine, if possible, which of these views is better justified, a series of investigations on meristematic tissue in perennials of different ages have been carried out, and this article is a brief preliminary statement of one of the more obvious results.

The structure of the adult leaves gives valuable insight into the meristematic tissue, since any minute changes occurring in the latter will be made larger and more obvious in the leaves, just as the inherent characteristics of seeds become more apparent in the plants into which they grow. If, therefore, the meristematic tissue of a perennial is changing with the increasing age of the plant, the new leaves appearing each year should reveal differences. In order to eliminate differences due to external factors, leaves were taken from cuttings of *Vitis riparia* of different ages grown under identical conditions. Comparisons were also made between leaves borne by vines growing wild, side by side under apparently identical conditions, and on many other kinds of trees and vines.

An interesting condition in the venation of the compared leaves was one of the results

noted and seemed to merit this preliminary note, because of the ease with which it may be recognized without apparatus by fruit growers as well as by botanists.

The smallest veinlets of the leaf form a continuous network and the meshes of this network are areas of parenchymatous tissue. The size of these areas is not only remarkably uniform in a mature leaf but is directly dependent upon the age of the plant upon which the leaf is growing. The older the plant, the smaller are the vein-areas of the leaf. This difference can be seen with a hand lens by holding the leaves up to the light. In *Vitis riparia*, for example, accurate measurements of hundreds of areas in leaves picked from different parts of the same vine, gave an average (vine 26 years old) area of .20398 sq. mm., while the largest measured .217 sq. mm. and the smallest .185 sq. mm. The comparison for leaves from vines of different ages is shown by the following table, which gives averages from leaves picked from many plants.

	4-5 Growth Rings.	6-12 G. R.	15-30.	35-50.
Cuttings of <i>V. riparia</i>44 sq. mm.	.35	.29	
Wild vines of <i>V. riparia</i>42	.33	.24	.16

Even where the leaves are very large, as in the case of those borne on water-shoots from living stumps, the size of the areas is that characteristic of leaves borne on the tree the age of the stump. One of the several series of this kind follows:

Tree of <i>Castanea dentata</i>	8 Rings	15 R., Water- shoot	30 R.	Tree 50 R.
Size of area.	.07 sq. mm.	.05 sq. mm.	.04 sq. mm.	.03 sq. mm.

The results with cuttings, water shoots and selected vines plainly indicates that the difference in size of areas is not due to external conditions. The reason that a leaf from a tree 25 years old differs in its venation from a leaf of a tree 10 years old is therefore that the meristematic tissue, in the two trees of the same species growing under the same conditions, is different. Apparently the meristem of the older tree produces less efficient spe-

cialized tissues than does the younger. The parenchyma is less permeable, the vessels less efficient in conducting; the sap must be brought into closer contact with all the leaf protoplasm. Since the amount of carbohydrate producing parenchyma is being gradually decreased by the inroads of the conducting system, the leaf is becoming a less efficient manufacturer of carbohydrate and ultimately the plant must starve.

If the changes in the size of the vein-areas be plotted as a curve, the nature of the resulting curve is the same as when the recognized senility changes in man and animals are plotted. It is interesting to note that changes in the vascular system in plants are due to the increasing senility of the meristem, just as changes in the vascular system of animals are due to senility. Dr. Osler says that "a man is as old as his arteries," and it may be said of plants that they are as old as their veins.

Since the leaves borne by cuttings showed but slight increase in the proportion of carbohydrate-producing tissue as compared with those on the original plant, it would appear that vegetative propagation can not and does not produce a young plant. The fact that the normal span of life for woody trees and vines extends in some cases over hundreds of years accounts for the fact that the approach of senility in vegetatively propagated plants is not more obvious. Plants which naturally reproduce by seed will tend to "run out" after long-continued vegetative propagation, ultimately dying of senility, and it is therefore incumbent upon our plant breeders to develop new varieties from seed, to take their place.

UNIVERSITY OF CINCINNATI

THE WASHINGTON MEETING OF THE AMERICAN CHEMICAL SOCIETY.

DIVISION OF INDUSTRIAL CHEMISTS AND CHEMICAL
ENGINEERS

G. D. Rosengarten, *chairman*.

F. E. Gallagher, *secretary*.

H. C. SHERMAN, D. A. BARTLETT and N. E. WEATHERLESS: *Relation of Ultimate Composition to Calorific Power in Coal*.

The analyses and calorific powers of 67 coals

from 17 states as published in Professional Paper 48 of the U. S. Geological Survey were considered. Estimates of calorific power by the usual formula

$$x = 8,080 C + 34,500 (H - \frac{1}{8} O) + 2,250 S$$

("Welter's rule")

gave results too low in seven eighths of the cases, the average result being 98.9 per cent. of the calorific power actually found.

The formula

$$x = 8,080 (C - \frac{1}{8} O) + 34,500 H + 2,250 S$$

("Walker's rule")

gave an average result 100.37 per cent. of the calorific power actually determined. The latter formula also showed a smaller proportion of serious errors in individual cases, and a smaller maximum error.

H. C. SHERMAN and S. H. REGESTER: *Relation of Proximate Composition to Calorific Power in Coal*. (Preliminary report.)

Analysis of the data for 500 samples of coal from different parts of the country are averaged to show the general course of the curve for calorific power of dry, ash-free substance with increasing proportions of volatile matter. As the proportion of volatile matter increases the mean deviations of individual samples from the average becomes greater. Where the volatile matter is over 48 per cent. of the dry ash-free substance the individual variations are so great as to deprive the average relation of any appreciable significance. Even with coals of low or moderate proportions of volatile matter, individual samples often differ from the average relation by 2 to 5 per cent. or more, so that if anything more than a crude approximation is desired the calorific power should be determined directly by combustion in a bomb calorimeter.

CHARLES E. MUNROE: *Note on the Production of Mercury Fulminate*.

Describes the preliminary steps taken in the production of substituted fulminic acids from the higher alcohols and of mercury fulminate and these substituted acids from acetaldehyde and the higher aldehydes.

CHARLES E. MUNROE: *The Present Status of the Gas Industry and Its Outlook*.

Attention was called to the fact that the centenary of the gas industry occurs in April, 1912, this being the one hundredth anniversary of the incorporation of the first Gas Light Company in London, England. The industry began in this country with the incorporation of the gas company in Baltimore in 1816. To-day there are 1,296

establishments in the United States, having a capital of \$915,537,000; employing over 50,000 persons; manufacturing 150,835,793 M. cubic feet of gas; and having a value for its products of \$166,814,000. To graphically depict the status and outlook of the industry a brief review of the various difficulties which it has encountered and the competitors which it has met and outranked was given, and it was admitted that the developments in the adaptation of electric energy to use presented now a more critical situation than the gas industry had perhaps ever before encountered; but he found in the development of the gas oven; in the employment of the chemical engineer; in the reduction of heat losses; in the more complete recovery of the by-products and their more complete utilization; and in the discovery and application of flameless incandescent surface combustion, means by which the gas industry could more than hold its own for a considerable time.

G. A. BURRELL: *New Forms of Gas Analysis Apparatus*.

This paper treats of gas analysis apparatus assembled by the author for work having to do with gas investigations carried on by the Bureau of Mines. Both accurate apparatus for use with mercury and apparatus for technical purposes are described. Exact and simple forms of apparatus for the examination of mine air and for use in ventilation studies are also described, both portable and laboratory forms. A special apparatus for the analysis of natural gas is also included. Also new apparatus for determining carbon monoxide by means of the iodic acid method.

F. M. WILLIAMS: *New Forms of Apparatus for Gas Analysis*.

J. T. BAKER: *Problems in Manufacture of C. P. Acids*.

This paper relates to the improvements made in recent years in the forms of apparatus for distilling acids on a larger scale. These are devised for working continuously by feeding the acid into the still as rapidly as the contents distills off and providing a gradual overflow for the tailings in order to remove the non-volatile impurities.

Apparatuses made of glass and porcelain are used and have a capacity of from 2,000 pounds to 4,000 pounds distillate in 24 hours. The advantages are less breakage with a minimum amount of labor and consumption of fuel.

J. R. CAIN and J. C. HOSTETTER: *A Rapid Method for the Determination of Vanadium in Steel, Ore, etc., based on its Quantitative Inclusion by the Phosphomolybdate Precipitate*.

Conditions are given for the quantitative precipitation of vanadium from solutions of steel, ores, etc., by coprecipitation with ammonium phosphomolybdate. Some methods of separating the vanadium from the precipitate are described. Attempts to determine the vanadium in the precipitate by Gregory's colorimetric method were unsuccessful. The vanadium may be reduced by sulphurous acid without reducing the molybdenum, and titrated against permanganate, but the method recommended by the authors is to reduce by hydrogen peroxide in concentrated sulphuric acid solution and titrate against permanganate, adhering closely to the conditions prescribed in the paper.

ERNEST BIDTEL: *Valuation of Fluorspar.*

Determinations usually required: Calcium-fluoride, silica, calcium-carbonate, sometimes lead, iron, zinc, sulphur.

Calcium-carbonate is determined by dissolving with ten per cent. acetic acid, taking the solubility of calcium-fluoride into consideration. Residue treated by yellow mercuric oxide to oxidize the sulphides, and silica volatilized by evaporation with hydrofluoric acid; loss in weight is silica.

Calcium-fluoride is eliminated without decomposing the ore. Iron oxide is transformed to iron-fluoride and separated together with lead and zinc sulphate by a solution of ammonium acetate containing ammonium citrate.

L. B. LOCKHAET: *The Quality of Commercial Kerosene.*

PERCY A. BOECK: *Notes on a New Form of Extraction Thimble.*

Notes collected from various investigators on a new type of inorganic extraction thimbles and filters known as alundum. Manufacture described. Articles are made from bonded alundum grain, which is the product of the fusion of bauxite in the electric furnace and is practically pure fused alumina. Any texture, filtering capacity, melting point, tensile strength, etc., for any purpose can be obtained by varying method of manufacture. Articles filter rapidly, without any previous preparation and without changing the concentration of the solution, absorb only slightly, require little washing, and can be cleaned and sterilized by dry heating. Several types of extraction and filtering appliances for various kinds of work mentioned.

JOHN P. SIMMONS and O. J. TEEPLE, Jr.: *The Effect of Filtration upon the Physical Properties of Petroleum Oils.*

FREDERIC P. DEWEY: *The Direct Determination of Small Amounts of Platinum in Ores and Bullion.*

Platinum alloyed with silver being soluble in nitric acid, the solution obtained in parting gold from silver in ordinary assays is treated with a limited amount of hydrogen sulphide, after roasting, the precipitate is cupelled with a small amount of lead and the bead parted in strong sulphuric acid. Any platinum present will be left as a white metal, generally recognizable as platinum, but it may be tested to prove its identity or the presence of platinum metals.

FRANKLIN PEALE SUMMERS: *The Product Patent.*

This paper deals with the differences existing between our patent laws and those of the other countries with reference to the product patent on foods, drinks and medicinals. Practically all the other countries with the exception of England and the United States refuse to grant a product patent on the commodities above mentioned. The result is that, first, they permit competition on the necessities of their citizens, and secondly, they encourage the growth of chemistry in the respective countries, by opening and keeping open new fields for chemical research.

As long as these alien countries will not grant to an American citizen the same privilege that the United States grants to their citizens, it does not seem equitable that we should continue to grant the product patent on foods, drinks or medicinals.

In so doing our country continues to retard the growth of chemistry in a field that the other countries keep open. Thus in one product, aspirin, our citizens are annually paying a tribute to Germany of approximately two hundred thousand dollars, over and above what this same commodity sells for in Canada where no product patent is valid. This is due to the fact that in England and Germany the field for the production of acetyl salicylic acid is an open one and competition is permitted.

Were our country to change its patent laws so as to conform with these other countries in this respect, it would open a vast field in the production of organic synthetic compounds. We would be enabled to compete with these countries in an industry whose financial return is many millions of dollars. We would also offer still further inducement for the chemist, and by so doing we would more than ever narrow down the handicap now held by Germany for supremacy in chemical fields.

JAMES O. HANDY: *The Use of Potassium Cyanide Solution in the Investigation of the Structure and Conductivity of Copper, Copper-covered Steel and Other Metals.*

A 25-per-cent. aqueous solution of potassium cyanide dissolves, when boiled, an amount of copper equal to 5 per cent. of the KCy used. Steel and iron are almost insoluble in the same solvent.

Copper containing iron or arsenic shows a characteristic crystalline and colored appearance when etched with KCy solution. Pure cast copper is but slightly affected.

The structure of the "welded on" or "alloyed on" copper coverings of copper-covered steel wire has been studied by means of KCy solution. The "alloyed on" coverings have shown their impure nature. The conductivity of the composite wires and of the bare steel cores (after dissolving off the copper by KCy solution) showed in one case as follows:

	Steel Per Cent.	Copper Per Cent.	Conductivity of Composite Wire Per Cent.
"Welded" ...	77.20	22.80	36.20
"Alloyed" ...	56.00	44.00	34.00

The conductivity of the steel cores approximated 14 per cent. The low conductivity of the sample highest in copper shows its inferiority.

E. P. HARDING and E. JOHNSON: *An Apparatus and Improved Method for Determining Quantitatively Hydrogen Sulfide in Illuminating Gas.*
H. E. KIEFER: *Free Lime in Portland Cement.*

This paper cites numerous experiments to show that free lime is not the sole cause of disintegration of Portland cement as shown by the boiling test. If free lime is a real cause, as little as three tenths of one per cent. will cause rupture. Shows that carbon dioxide is not essential to seasoning and that the absorption of as little as one tenth of one per cent. of water will under certain conditions cure a very defective cement. That under other conditions neither water nor carbon dioxide is essential. Advances a theory of disintegration on physical lines to account for the seasoning of unsound cements.

W. C. TAYLOR and E. C. SULLIVAN: *Glass Analysis.*

A rapid method for analysis of glasses has been developed, depending on the decomposition of the glass by means of hydrofluoric and oxalic acids. Results for alkalis agree very well with those given by the Lawrence Smith method and results for lead, alumina, iron, manganese, lime, magnesia and zinc are accurate also.

The method of Wherry for the determination of boric oxide has been applied to glasses with necessary modifications where zinc or lead is present.

GEORGE L. HEATH: *The Estimation of Absorbed Gases and Oxygen in Copper by Ignition in Carbon Dioxide and Hydrogen.*

Thirty-seven years ago Dr. W. Hampe, of Germany, devised a process for the quantitative estimation of the percentage of oxygen in commercial copper by heating flings, or drillings, in an atmosphere of pure hydrogen gas in a hard-glass bulb tube, determining the loss in weight of the metal, and as an alternative the weight of water produced by the union of the hydrogen with the oxygen existing in the copper. Archbutt, Hofman and the writer have improved the process, but there is an error and omission in all published accounts, which it is important to correct by announcing the results obtained in a recent search for a method to show us, not only the oxygen, but also the original absorbed gases in all refined, or cast, copper of trade, which mainly consists of hydrogen (as hydride, or solid solution), with traces of carbon monoxide, carbonic dioxide, nitrogen, and possibly argon.

A separation which is accurate enough for analytical purposes is made possible by heating the copper, first, in carbon dioxide, for absorbed gases; secondly, in hydrogen to take out the oxygen; thirdly, in carbonic acid for a short time to take out considerable residual hydrogen, which would be, otherwise, retained.

Copper absorbs and retains but traces of pure carbonic acid, so that gas will expel hydrogen under heat. The first and third propositions have, hitherto, been overlooked.

DIVISION OF FERTILIZER CHEMISTRY

Paul Rudnick, *chairman*

J. E. Breckenridge, *secretary*

PAUL RUDNICK (chairman's address): *Fertilizer Chemistry—A Report of Progress.*

The consumption of commercial fertilizers for the year 1910 is estimated, in round numbers, at about 5,750,000 tons, an increase of approximately 14 per cent. over that of 1909. The average annual increase in the past decade has been close to 11.3 per cent.

The cost of ammoniates which supply the nitrogen in fertilizers has materially advanced, as the demand is greater than the supply. Inorganic ammoniates, including nitrate of soda, sulphate of ammonia and the products made from atmospheric

nitrogen by chemical and electrochemical processes, are produced in constantly increasing quantities, but organic ammoniates, including tankage, blood, etc., can not be produced in sufficient quantity to meet the demand and can not be entirely replaced by the inorganic sources of nitrogen for reasons involving mechanical condition, so that the fertilizer may be applied to the soil by suitable machinery. Much care and thought should be given to methods of control by state fertilizer authorities, so that arbitrary methods of analysis may not prevent the utilization of organic ammoniates which are now being wasted and thus the cost of the necessary organic ammoniates be forced up beyond all reasonable bounds. This is a matter of conservation of resources as well. The nitrogen of practically all the coal burned in this country should be recovered in the form of sulphate of ammonia.

In striking contrast to the demand for high availability of nitrogen is the proposal to use raw phosphate rock, the phosphoric acid of which is admittedly not available or at least so slowly that its application does not pay. It is highly desirable that commercial methods of producing available phosphoric acid from phosphate rock by cheaper and more efficient means than by conversion into acid phosphate should be found, although the Wisconsin Agricultural Experiment Station has recently pointed out that the sulphur in acid phosphate, present as calcium sulphate and produced by the treatment of phosphate rock with sulphuric acid, is a very necessary element in fertilizers, as much as and in some cases more so, than phosphoric acid.

The German potash controversy has stimulated renewed activity in the search for sources of commercial potash salts in this country, so that we may not be dependent upon Germany for this important constituent. The U. S. Geological Survey is now engaged in drilling a well, at Fallon, Nevada, as it seems likely that such deposits may exist in that region.

After discussing the various theories proposed to explain the action of commercial fertilizers, the possibility is pointed out that the results obtained from the use of commercial fertilizers may in part be due to a protective action which they exercise on the cells of the plant in some way similar to the action of the salts in sea water on animal organisms.

The need of a comprehensive and scientifically accurate theory of fertilizers is pointed out, so that wasteful and unscientific use may give way

to the most efficient and economical, hence most profitable, use.

BURT L. HARTWELL and F. R. PEMBER: *The Effect of the "Wet Process" on the Availability of Low-grade Nitrogenous Materials.*

In all, two crops of Japanese millet, two of oats and one of buckwheat were grown in pots on two different soils which were supplied with all the necessary non-nitrogenous manures. The amount of nitrogen supplied in the various nitrogenous materials which were tested was the same for each crop. Hair tankage, garbage tankage and roasted leather were used both before and after being subjected to digestion in the presence of phosphate rock and sulfuric acid (the "wet process").

The nitrogen of the garbage tankage had a very low availability both before and after acidulation; while that in roasted leather and hair tankage, although of low availability before, was much more available after treatment.

The treatment by the "wet process" of these nitrogenous materials individually was conducted in the laboratory, but a mixture of the three was treated by the regular "wet process" in a fertilizer factory. Over 70 per cent. of the nitrogen in the "base goods" so manufactured was soluble in water and highly available, but the insoluble nitrogen was of no immediate value.

F. B. PORTER: *A Method for Testing Out Problems in Acid Phosphate Manufacture.*

1.1 grams rock dust are weighed into 5" × 3/4" test tube, known amount of acid added from Mohr's pipette. Stir three minutes, keep at any desired temperature for any desired time.

Transfer on to 9 cm. filter paper with water and determine insoluble phosphoric acid.

Average of three or four tests taken for result.

I. K. PHELPS: *Exact Work in Fertilizer Analysis.*
C. H. JONES: *Activity of Organic Nitrogen as Measured by the Alkaline Permanganate Method.*

The alkaline permanganate method for nitrogen activity is described in detail, together with the form now used for reporting results.

Results on fourteen different crude nitrogenous stock samples, 8 commercial fertilizers, and 13 mixtures of known composition are stated in tabular form, and explanations are given as to their interpretation from a standpoint of nitrogen activity.

A method is presented for determining the percentage of "nitrogen in the organic and volatile matter." Its application to fertilizers and crude stock as a means of determining whether the

organic nitrogen present came from materials rich or poor in that element is discussed.

H. G. BELL: *Fertilizer Economics.*

Advantages of mixed fertilizer are brought forth.

The fertilizer industry an essential factor in the business and life of the country.

European and American yields on wheat, oats, barley and potatoes are compared, showing Europe far ahead in crop yields.

North Atlantic states compared with middle Atlantic states shows gains for north Atlantic states in yield per acre due to rational use of mixed fertilizer.

Records of large gains by using fertilizer are given in Indiana and Ohio.

Sound economic principles as the basis of manufacture and sale of fertilizer are considered.

E. B. HART: *The Sulphur Requirements of Crops in Relation to the Soil and Air Supply.* (From the Laboratory of Agricultural Chemistry, University of Wisconsin.)

The average crop of cereal grains and straws removes about two thirds as much sulphur as phosphorus, mixed grasses remove the two in about equal proportions, while alfalfa removes about 60 per cent. more sulphur than phosphorus. Members of the Cruciferae, such as cabbage and turnips, may remove two to three times as much sulphur as phosphorus.

The superior results often obtained in the case of acid phosphate as compared with other sources of phosphoric acid may not be due entirely to the solubility of the phosphoric acid, but also to the additional sulphur supplied by the acid phosphate in the form of calcium sulphate. The idea that sulphur may become a limiting element in crop production would further account for the beneficial results obtained from gypsum, sulphate of potash and other sources of sulphur commonly contained in fertilizers.

J. P. STREET: *Note on the Neutral Permanganate Method for Availability of Organic Nitrogen.*

The adding of one gram of sodium carbonate to the neutral permanganate solution just before adding material to be tested largely overcomes the loss in availability when high-grade ammoniates are mixed with large proportions of acid phosphate.

Results on many organic ammoniates in presence of acid phosphate are given, showing that the method does differentiate between high and low grade materials.

A. J. PATTON and C. S. ROBINSON: *Conductivity Method of Making Neutral Ammonium Citrate Solution.*

This method, worked out independently by the authors, is essentially the same as that proposed in the meantime by Hall and Bell¹ and later shown by Hall² to be quite suitable for ordinary laboratory use, and their results are fully confirmed by this work. In addition comparative determinations of insoluble phosphoric acid were made, using solutions neutralized by the conductivity method and by the indicator method. The data justified the conclusion that the conductivity method is much to be preferred in every way to the indicator method.

DIVISION OF PHYSICAL AND INORGANIC CHEMISTRY

H. P. TALBOT, *chairman*

S. L. BIGELOW, *secretary*

JAMES R. WITHROW: *The Relative Densities of Sodium Amalgam and Mercury.*

R. B. MOORE: *The Formation of Helium from the Thorium Emanation.*

A. B. DAVIS, IVY MILLER and R. B. MOORE: *Nipponium.*

H. H. WILLARD: *The Quantitative Separation of Lithium from Sodium and Potassium.*

Sodium and potassium may be separated from lithium by precipitation as silicofluoride in methyl alcohol solution. Ethyl alcohol and acetone cause a large amount of lithium to be precipitated with the sodium and potassium. To the solution, which should be very small in volume—not over 10 c.c.—is added a little hydrochloric acid, then hydrofluosilicic acid, and 75 or 80 c.c. methyl alcohol. Several hours are required for complete precipitation. If the amount of lithium is large, the precipitate must be dissolved and reprecipitated. It may be dried at 150°–180°.

Lithium may be quantitatively precipitated from a neutral solution by means of tribasic tetramethyl-ammonium phosphate, methyl alcohol being added to make the precipitation more complete. If present in considerable amount, a little sodium is carried down, but a second precipitation will give a complete separation.

H. H. WILLARD: *The Preparation of Perchloric Acid.*

Ammonium perchlorate is oxidized by means of nitrohydrochloric acid, the ammonium being thus

¹ *Jour. of the Am. Chem. Soc.*, 33, p. 711, 1911.

² *Jour. of Ind. and Eng. Chem.*, 3, p. 559, 1911.

removed and perchloric acid remaining. The best proportions are: 1 kg. ammonium perchlorate, 800 c.c. water, 600 c.c. nitric acid (sp. gr. 1.42), 200 c.c. hydrochloric acid (sp. gr. 1.2). The hydrochloric acid is added slowly to the boiling solution of the other substances, using a reflux condenser. After about one hour the solution is evaporated until all nitric and hydrochloric acid is removed. The yield is the theoretical.

CHARLES H. WHITE: *A Colorimeter for Rapid Work with Widely Varying Standards.*

The standard and the unknown solution are compared in hollow wedge-shaped prisms of glass, placed vertically in a camera behind screens provided with a narrow horizontal opening opposite the eye for the simultaneous observation of the two solutions. The wedges are held in graduated carriers, by the vertical movement of which the thickness of the section of solution observed is varied. The wedge containing the unknown is set at the graduation representing the percentage of color-producing agent in the standard. The standard is then adjusted to match the color of the unknown and the percentage in the unknown is read directly.

IRVING LANGMUIR: *The Dissociation of Hydrogen into Atoms at High Temperatures.*

In a previous paper (to be published in the *Phys. Rev.*) it was shown that the laws of heat convection in gases are much simpler than has been generally supposed. In fact, the problem reduces to one of simple conduction through a film of relatively stationary gas held in place by viscosity. The thickness of the film in any gas under any given conditions may be calculated accurately by simple formulas. If the energy loss for a tungsten filament in hydrogen be calculated in this way the results agree with observed values within the experimental error up to a temperature of about 2300° K., but above this show rapidly increasing differences. At 3300° K. the observed energy loss is over four times the calculated. It is assumed that this difference is due to the dissociation of hydrogen molecules into atoms. The variation of the energy loss with the temperature and with the pressure agree quantitatively with this theory. Simple unforced theoretical considerations form the basis for a calculation of the heat of formation of hydrogen molecules and the percentage dissociation at various temperatures. The results are: Heat of formation of H_2 , 125,000 cal. Percentage dissociation (1 atmo.): at 2500° K. 3.9; 2700°, 10.0; 2900°, 22.1; 3100°, 40.4; 3300°,

61.4. In the case of the monatomic gas, Hg vapor, the calculated energy loss does not show differences with the observed values similar to the above.

IRVING LANGMUIR: *A Chemically Active Modification of Hydrogen.*

When a tungsten wire is heated to a temperature between 1300° and 2500° K. in hydrogen at very low pressure (0.001–0.020 mm.) the hydrogen slowly disappears. With nitrogen or carbon monoxide such disappearance never occurs below about 2200° K. and seems to be an electrical effect, while with hydrogen it is purely thermal. There is a distinct fatigue effect, but the substitution of a new section of wire does not restore the action. The hydrogen is not absorbed by the wire, but is deposited on the glass, especially where the latter is cooled by liquid air. If the wire is allowed to cool and the liquid air is then removed, ordinary hydrogen is set free which will not recondense when the liquid air is replaced. If this gas is pumped out and oxygen is admitted the oxygen will disappear and in its place a small quantity of hydrogen will appear. With platinum and especially with palladium wires these effects are much more marked. These effects are not due to the presence of finely divided metal on the surface of the glass. When phosphorus is present on the inner surface of the bulb and hydrogen is introduced and the wire heated to a temperature of about 1900° K., the hydrogen disappears and phosphine is formed (apparently the first direct synthesis of phosphine). These effects are accounted for by the theory that the hydrogen dissolves in the material of the wire in the atomic condition and that some of these atoms leaving the wire, do not meet other atoms (because of the low pressure) but diffuse into the tube cooled by liquid air, or become adsorbed by the glass, and thus remain in the atomic condition, retaining all of the chemical activity of the atoms.

IRVING LANGMUIR: *Melting Point of Tungsten.*

The melting point was determined by heating pure ductile tungsten wires in pure hydrogen to gradually increasing temperatures until the wire melted through. The temperature was found from the candle power emitted per square mm. of surface, using a modified form of Rasch's equation. The advantages of an atmosphere of hydrogen are: (1) Vaporized metal is carried away by the hydrogen and does not blacken the tube and interfere with candle-power measurements. (2) The energy loss from small wires in hydrogen is nearly independent of the diameter of the wire, therefore

if the wire becomes thin in one spot the tendency to burn out is much less than it would be with the wire run in vacuo. It is therefore possible to make reliable measurements of the candle power at a temperature much closer to the melting point than is possible in vacuo. The results were: in hydrogen 3250° K., 3345°, 3430° and one somewhat doubtful value of 3500°; in mercury vapor, 3450° K. and 3350°. As the method tends to give low results it is highly probable that the melting point of tungsten is at least 3500° K. or about 3250° C. This is in good agreement with the value given by Pirani 3300° C., but very different from that of von Wartenberg, who gave 2900° C.

JOEL H. HILDEBRAND: *The Thermal Dissociation of Barium Peroxide.*

This equilibrium has been investigated on account, not only of its scientific interest, but because of its practical application in the manufacture of oxygen and hydrogen peroxide.

The nature of the phases involved was determined by observing the effect upon pressure of removing successive portions of oxygen, the temperature being kept constant. It was shown that within certain limits the oxide and peroxide form solid solutions in each other, and that a barium hydroxide phase must also be present. Conditions for reversing the equilibrium were stated.

Accurate measurements of the dissociation pressures of the univariant system were made, and the thermodynamics of the system discussed.

S. C. LIND: *Chemical Combination and Disintegration under the Influence of Radium.*

Chemical action produced by radium is due almost entirely to the α -rays. For gas reactions both of combination and of disintegration the number of molecules affected in a given time is of the same order of magnitude as the number of ions formed by the α -rays in that time, as calculated from Bragg's experiment on the ionization of gases. Data of Ramsay and of the author verify this conclusion with respect to radium emanation. A method is proposed for calculating simply the mean path of α -rays in cylindrical and spherical vessels. The principle found true for gases may also be extended to liquid systems, data of Ramsay, of Debiérne, and of the author being used for its establishment both for emanation and radium salt in solution.

EUGENE C. BINGHAM: *Fluidity and Vapor Pressure.*

E. C. BINGHAM and G. F. WHITE: *Fluidity and Hydration.*

E. C. BINGHAM and G. F. WHITE: *A New Viscosimeter.*

EDWARD C. FRANKLIN: *Potassium Ammono Thallate.*

When the ammonio base, potassium amide, in solution in liquid ammonia is added to a solution of thallium nitrate in the same solvent a black precipitate of thallium nitride is formed in accordance with the equation,

Thallium nitride dissolves in a liquid ammonia solution of potassium amide to a clear yellow solution from which potassium ammonio thallate of the composition represented by the formula, $\text{TlNK}_2 \cdot 4\text{NH}_3$, may be obtained in the form of beautiful yellow crystals. The action of potassium amide on thallium nitride is represented by the equation,

WILLIAM BLUM: *The Hydrolysis of Sodium Oxalate and its Influence upon the Test for Neutrality.*

The testing of sodium oxalate for use as a primary standard in acidimetry and oxidimetry requires a knowledge of the normal alkalinity. Decimolar solutions of pure sodium oxalate were found to produce a pink color with phenolphthalein equivalent to 4 per cent. transformation of the indicator, instead of the calculated 8 per cent., showing discrepancies in the accepted constants or theories. Colorimetric comparisons were made with solutions calculated from Sørensen's E.M.F. measurements, indicating that for 0.1 *m* $\text{Na}_2\text{C}_2\text{O}_4$, $[\text{H}^+]_{1:10} = 2.5 \times 10^{-9}$; and that the salt is hydrolyzed to the extent of 0.0024 per cent. The error produced in a titration by neglecting this normal alkalinity is negligible.

R. C. WELLS: *The Fractional Precipitation of Hydroxides.*

By fractionally precipitating dilute solutions of various pairs of metallic salts with caustic soda the following series was obtained, such that the higher members are more precipitable: ferric, aluminum, copper, zinc, lead, nickel, silver, ferrous, manganese, magnesium, calcium. The position of a metal in the series is probably determined by (1) the solubility of the hydroxide and (2) the extent of hydrolysis of the metallic salt. The series agrees well with the order of the heats of precipitation of the hydroxides.

C. W. EASLEY and B. F. BRANN: *The Atomic Weight of Mercury.*

By means of bringing an excess of pure bromine in contact with pure mercury at approximately 300°, mercuric bromide was sublimed into a convenient receiver, which in turn was heated almost to the point of sublimation of the material in a stream of nitrogen. On cooling, the nitrogen was displaced by dry air.

From this material, mercuric oxide was precipitated by the use of a slight excess over the calculated amount of sodium hydroxide. This action was brought about in a flask with well-guarded openings so that the subsequent reduction with hydrogen peroxide or with hydrazine gave rise to no loss of the solution in the form of spray. The solution being separated from the free mercury, the bromine was determined as silver bromide in the usual way. The value 200.63 was obtained as the result of eleven concordant determinations of the ratio $\text{HgBr}_2 : 2\text{AgBr}$, no determinations, of course, being rejected.

J. I. D. HINDS: *Precipitation of the Copper-Arsenic Group and the Separation of its Divisions.*

A definite acid concentration is secured. Arsenic is precipitated in 2 normal hydrochloric acid solution, the other metals in half normal hydrochloric acid solution. Tin is precipitated as stannic sulfid. The sulfids of arsenic, antimony and tin are dissolved in colorless ammonium sulfid, or in ammonium hydroxid and hydrogen sulfid.

To a portion of the solution add one ninth its volume of hydrochloric acid (making it normal in HCl since the laboratory acid is about 10 normal) and a few drops of nitric acid to oxidize stannous to stannic ion. Boil the mixture a little more than half away in an Erlenmeyer flask, making the residual liquid 2 normal, pass a rapid stream of hydrogen sulfid until precipitation is complete (5 to 10 minutes), add enough water to make the volume twice the original, making the solution one half normal in hydrochloric acid and continue to pass hydrogen sulfid until precipitation is complete (10 to 15 minutes). Filter and wash.

Transfer the precipitate to a beaker, cover it with ammonium hydroxid, pass hydrogen sulfid rapidly for a minute, warm, shake, filter and wash. The filtrate contains the thioanions of arsenic, antimony and tin; the residue contains the sulfids of the other metals of the group.

Treat filtrate and residue in the usual way.

Time required for the entire process 30 to 45 minutes.

WILLIAM D. HARKINS: *The Intermediate Ion Hypothesis.*

The values now used for the degrees of dissociation of univalent salts, such as K_2SO_4 , BaCl_2 or $\text{Cu}(\text{NO}_3)_2$, do not represent the degrees of dissociation at all, but are only the values of the conductance ratio, if intermediate ions are present in the aqueous solutions of salts of this type. In recent papers* it has been shown that the solubility relations of such salts indicate that the ionization takes place in two steps as follows:

Potassium sulphate, according to the present values used, is 71 per cent. dissociated in its tenth normal solution at 25°. Approximate calculations made upon the basis of the intermediate ion hypothesis indicate that its actual total dissociation is about 95 per cent.

It seems probable that all triionic salts, acids and bases, when dissolved in water, dissociate in two steps, and that intermediate ions are present in all such solutions. If this is the case, it seems self-evident that intermediate ions must be present in all aqueous solutions containing salts, acids or bases of still higher types. The percentage of the salt present as the intermediate ion is zero at zero concentration and increases as the concentration of the salt in the solution increases.

The constant $k = (\text{K}^+ \times \text{KSO}_4^- / \text{K}_2\text{SO}_4)$ increases with the total ion concentration and is several times larger, in the case of salts, than the second constant $k = (\text{K}^+ \times \text{SO}_4^{--} / \text{KSO}_4^-)$.

Solutions of certain salts, such as lead chloride, contain an abnormally large percentage of the intermediate ion.

G. R. WHITE and H. EASTWOOD: *Electrolytic Corrosion in Ammonium Salts.*

Test pieces of copper, nickel, zinc, tin, iron and cadmium were made anodes in solution of ammonium chloride, sulphate, nitrate, acetate and tartrate containing 75 g. of the salt per liter. The anodes were rotated to ensure thorough stirring. The electrolysis was carried on at room temperature for an hour with a current of .35 amp. The average current density was 2.8 amp. per sq. dm. The results, which are given as percentage efficiency of corrosion, show that corrosion is markedly different for different electrolytes and that it is affected by changing the current density and in some cases by changing the temperature.

J. W. TURBENTINE and RAYMOND L. MOORE: *Contributions to the Electrochemistry of Hydro-*

* *Jour. Am. Chem. Soc.*, 33, pp. 1807-73.

nitric Acid and its Salts. II. The Action of Copper and of Cuprous Oxide on Hydronitric Acid.

In order to test the plausibility of certain reactions proposed to account for the phenomena observed at magnesium, aluminium and zinc anodes in sodium trinitride solution, reactions analogous to those hypothesized were induced and the accompanying phenomena were examined. The action of cuprous oxide on hydronitric acid is that of a reducing agent, the acid being reduced to ammonia and free nitrogen and the cuprous oxide becoming cupric trinitride. The relations here existing may be represented qualitatively by the expression: $\text{Cu}_2\text{O} + 5\text{HN}_3 = 2\text{CuN}_3 + \text{H}_2\text{O} + \text{NH}_3 + \text{N}_2$. With metallic copper, cupric trinitride results, and ammonia and gaseous nitrogen again appear as the reduction products. To represent this reaction, the equation is given:

J. W. TURRENTINE and LEONARD A. MAYNARD:
The Reduction of Hydronitric Acid by Cadmium.

Hydronitric acid dissolves cadmium with effervescence. A neutral solution of cadmium trinitride and ammonium trinitride results. The gas evolved is nitrogen. The following equation is proposed to represent the course of the reaction:

The products of the reaction have been measured. In the reactions with cuprous oxide, copper and cadmium (and with numerous other substances), hydronitric acid is found to be an oxidizing agent, an analogue of nitric acid, a fact which leads to an analogous structure. Accordingly, the structural formula for hydronitric acid, $\text{H}-\text{N}=\text{N}=\text{N}$, is proposed, analogous to that of nitric acid,

This structure is supported by numerous reactions and considerations yet to be presented. Just as nitric acid is regarded as a hydrated oxide of nitrogen, hydronitric acid may be considered an ammoniated nitride of nitrogen.

E. H. ARCHIBALD: *The Hydrolysis of Potassium Chloroplatinate.*

The hydrolytic decomposition of solutions of potassium chloroplatinate at a temperature of 25° has been studied. The hydrolysis can be followed by titrating the hydrochloric acid formed with sodium hydroxide, using phenolphthalein as indicator.

The hydrolysis takes place very rapidly under the influence of light, apparently the ultra-violet rays only being concerned, as no action is caused by the strongest illumination from four Welsbach mantles. In bright sunlight at a temperature of 25° the reaction is complete in the case of a *N*/50 solution in 200 minutes when an amount of hydrochloric acid will have been formed equivalent to 36.5 per cent. of the chlorine present as platinum tetrachloride. A solution of this strength prepared in non-actinic light and kept in the dark has not attained equilibrium before several weeks. In the case of a hundredth normal solution the time required for equilibrium to be established in bright sunlight is 175 minutes and hydrochloric acid is formed corresponding to 50 per cent. of the chlorine present as platinum tetrachloride.

The reaction reverses to a small extent when the solution hydrolyzed by the bright sunlight is placed in the dark.

The reaction reverses much further, rapidly in the light but very slowly in the dark, when potassium chloride is added to the hydrolyzed solution.

E. H. ARCHIBALD and E. F. CONWAY: *The Hydrolysis of Potassium Bromoplatinate.*

The hydrolysis of potassium bromoplatinate has been studied after the manner of the previous investigation. The source of the ultra-violet rays was in this case an electric arc placed about 25 cm. from the solution to be studied. The temperature was kept constant at 25°. The hydrolysis is more complete than in the case of the chloroplatinate; the amount of hydrobromic acid formed in a *N*/100 solution corresponded to 78 per cent. of the bromine present as platinum tetrabromide. The reverse reaction also goes further when the hydrolyzed solution is placed in the dark.

A solution of the bromoplatinate prepared in the absence of actinic rays and kept in the dark showed no detectable hydrolysis after five days.

H. C. COOPER, E. H. KRAUS and A. A. KLEIN:
Lead Silicates.

Having subjected the system $\text{PbO}-\text{SiO}_2$ to thermal analysis and optical analysis, the latter particularly difficult because the refractive indices of most of the lead compounds are higher than the index of any known immersion liquid, the authors conclude that PbSiO_3 , Pb_2SiO_4 and $\text{Pb}_3\text{Si}_2\text{O}_7$ are well-defined compounds and that Pb_3SiO_5 is probably also an independent substance. The minerals barysilite, found in Sweden by Sjögren and Lundström and the mineral alamosite, recently described independently by Palache, correspond fully

with the compounds $\text{Pb}_2\text{Si}_2\text{O}_7$ and PbSiO_3 , respectively. It is interesting that the artificial alamosite was prepared and characterized before its counterpart was found in nature. The crystallized lead silicate formations found under dismantled smelters are rather miscellaneous in character, the largest crystals being of mixed composition.

H. S. FAY: *Some Application of the Electronic Conception of Positive and Negative Valencies: V. Dynamic Formulæ and Absorption Spectra of Chlor- and Brom-benzene.*

F. D. WILSON: *A Further Study of the Action of Calcium Carbonate on Zinc Sulphate Solutions.*

When calcium carbonate and zinc sulphate solutions are brought into contact with one another in varying preparations, and at different temperatures, and for different periods of time, the basic carbonate is formed.

When the solution of zinc sulphate is changed into carbon dioxide, and calcium carbonate added, and carbon dioxide passed in for several days, the normal carbonate of zinc with from 0.8 to 1.5 per cent. of water is formed.

ROBERT B. SOSMAN: *The Nitrogen Scale from 300 to 600 Degrees.*

CHARLES BASKERVILLE and ABRAHAM LUSKIN: *Chemical Tests for Lanthanum.*

As far as we are aware, there are no chemical tests for lanthanum which are so distinctly characteristic as to be used to prove the presence of that element when associated in mixtures with neodymium or praseodymium. Recourse must be had to photographic reproduction of the arc or spark spectrum, facilities for which do not constitute a part of the armamentarium of all analytical chemists, and at best this is not applicable upon a quantitatively qualitative basis.

Having exhausted the probabilities of analogous tests for other metals, recourse was had to the empiricism offered by a Kahlbaum catalogue. While much not recorded in the literature was observed as to the conduct of this subgroup of the so-called rare earths with many unusual reagents, the main object was to secure some one or more definitely distinctive tests for lanthanum alone or in mixtures. While it may be stated that results altogether satisfactory were not obtained, the following may be noted.

Conduct with Sodium Potassium Tartrate.—Solutions of lanthanum, neodymium and praseodymium salts, singly or mixed with each other,

give precipitates with this reagent which dissolve in an excess of the precipitant. On adding oxalic acid to these solutions a precipitate is produced in each case, but with lanthanum the precipitate is soluble in excess. Filtration, evaporation and ignition yield lanthanum oxide. The delicacy of the reaction and all the determining factors have not been established.

Conduct with Cyanates.—Potassium cyanate gives a white gelatinous precipitate insoluble in excess. On standing the precipitate changes into beautiful silk-white crystals. Similar conduct was observed with neodymium and praseodymium salts, except that each of the latter exhibited the characteristic rose or light green tint. The solubility of these cyanates, the composition of which has not been determined, was investigated, using a great variety of solvents, some very unusual. A difference was noted in the solubility in bromine water, the lanthanum salt being more soluble. In acetic acid, however, the lanthanum salt dissolved much more slowly. The same was noted with lactic and phthalic acids and boiling sodium tartrate solutions. In the last the neodymium preparation is entirely soluble, whereas the lanthanum salt is only slightly, but appreciably, soluble.

Neither of the methods has so far shown itself suitable either for satisfactory qualitative purposes or for separating lanthanum from the didymium on a laboratory scale.

Suggestions as to rarely applied tests will be most acceptable.

CHARLES BASKERVILLE: *On the Simplicity of Praseodymium.*

The results of twelve years' study of praseodymium with different assisting workers in an effort to show its complexity are given. All efforts to decompose praseodymium were unsuccessful. The investigations were carried out along the following lines: (1) fractional precipitation from salt solutions; (2) fractional solution of the black oxide in acids; (3) fractional decomposition of the nitrate by heat; (4) fractional crystallization of double nitrates, one being an isomorphous nitrate of another metal; (5) fractional oxidation of a soluble salt of praseodymium; (6) fractional oxidation of the oxide by fusion with an alkali peroxide, and (7) fractional electrolysis, with and without a porous cell. The absorption spectrum of the different fractions, several thousand all told, was taken as a criterion as to any disintegration. Solutions of a definite strength, acidity and thickness were compared.

J. E. MILLS: *Force*.

Elasticity is a property very similar to temperature, depending upon the motion of certain parts of larger elastic bodies. When these fundamental particles collide they simply exchange velocities instantaneously. Neither motion nor energy is for a fraction of a second lost.

The usual definition of force is: "A unit force is that force which, acting on a mass of one gram for one second, will give to it a velocity of one centimeter per second." In a medium when the particles exchange their velocities instantaneously this definition of force does not apply, as the words "for one second" have no meaning. More important is the fact that the kinetic energy of a moving body must then be measured by its mass (probably amount of matter) times its velocity, instead of by one half its mass times the square of its velocity.

The term "attractive force" has been applied to chemical, molecular, gravitational, electrical and magnetic attractions. Some in consequence of our definition of force have invested these phenomena with attributes which they do not possess.

W. E. HENDERSON: *A Jacket for a Victor Meyer Apparatus*.

The usual form of glass jacket is replaced by a beaker deep enough to contain the bulb of the inner tube. The beaker is covered with a copper sheet in the center of which is a circular hole large enough for the insertion of the bulb. Concentric with this hole is a deep groove in the cover in which the square end of a piece of large glass tubing rests in a water seal (a broken outer jacket cut square will serve). The beaker should have no lip.

W. E. HENDERSON and H. B. WEISER: *The Action of Sulphurous Acid upon the Sulphides of Iron and Manganese*.

When freshly prepared sulphides of iron or manganese are treated with sulphurous acid the primary action appears to be the production of the metallic sulphites and hydrosulphuric acid. The sulphites are held in solution as acid salts, and are precipitated as normal salts on warming the solution. The interaction of sulphur dioxide and hydrosulphuric acid produces free sulphur which converts a portion of the sulphites into thiosulphates. These have been isolated in pure form. Contrary to the statements in the literature, there is no dithionate or tetrathionate formed beyond possibly a mere trace.

R. F. BRUNEL: *The Equilibrium between Iso and Tertiary Butyl Bromides*.

CHAS. T. P. FENNEL: *A Strange Substance in Iodine*.

A. S. MCDANIEL: *Chemistry of the Silver Volt-ammeter*.

CHAS. A. KRAUS and WM. C. BRAY: *A General Law of Ionization of Binary Electrolytes*. (Presented by Wm. C. Bray.)

From a preliminary examination of the existing conductance data in various solvents the first named author four years ago suggested the relation

$$\frac{(C\gamma)^2}{C(1-\gamma)} = K + D(C\gamma)^m,$$

where C is the concentration, γ the degree of ionization calculated from the conductance ratio Λ/Λ_0 , and K , D , m are constants. A more careful study, which is still in progress, has furnished striking confirmations of this law. The evidence that the law of mass action is obeyed in dilute solutions is based on the experimental results of Franklin and Kraus in liquid ammonia and of Dutoit and his coworkers in propyl, butyl and amylalcohols and in acetone, sulfur dioxide, pyridine, etc. There is a rough parallelism between the values of K for a typical salt (as NaI) and the dielectric constants of the pure solvents. The deviations from the law of mass action are in general appreciable when the ion concentration is greater than 0.0005 normal. The values of m usually lie between 0.4 and 0.6 in aqueous solution and between 0.9 and 1.2 in liquid ammonia and are still larger in solvents of lower dielectric constants. Whenever m is greater than 1, the values of the equivalent conductance pass through a minimum as the concentration increases and then increase with increasing concentration. D is the controlling factor in determining γ at high ion concentration, and usually lies between 0.1 and 5.0 for the different solvents. The above law ceases to hold in the neighborhood of normal concentration, and Λ then decreases with increasing concentration. There is evidence that this decrease is connected with the rapidly increasing viscosity of these concentrated solutions.

HARRY N. HOLMES: *The Detection of Ozone*.

The paper presented the various theories explaining the presence of ozone in nature and gave the results of six months' ozone tests in outdoor air. In June and July the quickest response to a starch potassium-iodide test was an hour and a

quarter, except in the case of a thunder-storm, when the record was set at fifteen minutes. In the hottest days of July no test at all could be obtained and none at night in either month. This would seem to indicate that the ultra-violet rays of sunlight have a great deal to do with the formation of ozone.

In the bracing days of late November the weather was cold and snappy. A test resulted in less than twenty-five minutes on November 13. During the following three weeks several tests were secured in thirty or forty minutes. At this time the silent electric discharge between earth and clouds must have been quite instrumental in forming the ozone. The greater stability of ozone in cold weather allowed it to accumulate.

Probably after a cyclonic disturbance of the upper air we on the surface get a supply of ozone manufactured in the upper laboratories. On the occasion of some of the above tests air was drawn over crystals of chromic acid to eliminate the effect of hydrogen peroxide. Furthermore, delicate reagents for hydrogen peroxide and nitrites failed to yield a test. The inference is that all the above tests were due to ozone alone.

W. M. BLANCHARD: *A Simple Lecture Apparatus for Illustrating the Relative Ionizations of Salts.*

ARTHUR B. LAMB and JOHN W. MARDEN: *The Quantitative Determination of Perchlorates.*

The determination of perchlorates by fusion has, in spite of its great simplicity, been generally abandoned in favor of some method of reduction in solution. This has been due to the fact that during ignition or fusion there have been small but apparently unavoidable mechanical losses, presumably of potassium chloride. The authors have shown that by merely carrying on the fusion in a test tube, suitably plugged with asbestos wool, instead of in a crucible, these losses could be prevented, and by precipitation of the chloride as silver chloride a very simple but accurate determination of the perchlorate obtained.

G. N. LEWIS and F. G. KEYES: *The Potential of the Potassium Electrode.*

G. N. LEWIS and PAUL FARRAGHER: *Potentials between Liquids.*

J. E. SIEBEL: *The Molecular and Intermolecular Energy.*

In this paper the author attempts to show that, " PuV " being practically equal to " ExT " for permanent gases, no notable portion of the kinetic energy can be present therein as rotary or intermolecular motion, since neither of these motions could contribute to the pressure and volume energy, of which a full equivalent appears for every amount of heat or kinetic energy imparted to a gas, and that therefore all kinetic or heat energy of gases must be almost exclusively due to the translatory motions of the molecules, while other internal molecular motions must be confined to chemical, radiant and other energies. Confirmatory of this the author also finds that the translatory molecular velocity in gases calculated on above basis, after different independent methods, is uniformly almost exactly double that of the velocity of sound in the respective gases, thereby indicating another mode of propagation of sound in addition to that by aerial resonance, in which new mode of propagation the molecular vibrations act as vehicle for the sound impulses, which new mode of propagation would fully explain all acoustic phenomena, including also such (audibility of very feeble sounds for miles, etc.) not explainable by aerial resonance only.

A. A. NOYES: *A Proposed System of Notation of Physico-chemical Quantities.*

JOHN JOHNSTON: *A New Form of Mechanical Vacuum Pump.*

This pump—known as the May Nelson Rotary Pump—consists essentially of two plates of metal, one fixed, the other movable; no valve, packing or fluid is required, though a little lubrication is desirable for mechanical reasons. A somewhat defective pump of this type has given a vacuum of 0.01 mm. when connected to the gauge by rubber tubing. It has exhausted 6 liters to 0.1 mm. in 2 minutes. After pouring in 1 c.c. of water, the pressure was reduced to 0.5 mm. in 4 minutes, without drawing any air through the pump. The exact mode of working is difficult to show without a diagram, but the principle may perhaps be made sufficiently clear by what follows:

In each of the metal plates are cut a series of concentric grooves, which are so situated that the projections on each plate will lie in the grooves on the other plate. Through the center of the fixed plate passes a shaft, on which is an eccentric carrying the movable plate. Rotation of the shaft thus produces an eccentric motion—but no rotation—of the movable plate; as a result there is,

between each adjacent pair of curved surfaces, a rolling contact which sweeps out the air ahead of it. The pump above mentioned has an inner diameter of 13 cm., a depth of 4 cm., and consists of three rings which pump in series; the speed of rotation of the shaft was 800 r. per minute; $\frac{1}{2}$ H.P. suffices to operate it.

The effectiveness of this form of pump appears to be due to two things: (1) A very slight travel of the metal parts produces a relatively rapid motion of the crescent-shaped spaces between the rings on the two plates; (2) the contacts, since they occur between curved surfaces of nearly the same radius, are relatively long; hence the viscosity of the air is sufficient to prevent appreciable leakage backwards.

This pump may also be operated as a blower, or, with slight modifications, can be used as a water motor; indeed, since the rings may be made independent of one another, one can drive the pump by supplying water to one ring and obtain vacuum or blast from the other rings.

SECTION OF INDIA RUBBER CHEMISTRY

D. A. Cutler, *chairman*

F. J. Maywald, *secretary*

W. A. DUCCA: *Testing Methods of Rubber Contents in Raw and Vulcanized Rubber.*

The paper deals with modern methods of rubber analysis by nitrosate and tetrabromide methods. Mostly a historical review of the work done along these lines. In accordance with his own experiences the author concludes that the nitrosate method is not suitable for the determination of rubber in either raw or vulcanized samples, but yields apparently satisfactory results for sulfur of vulcanization. Budde's tetrabromide method gives a fair idea of the percentage of actual rubber in samples of raw material, but is not applicable for vulcanized goods. Huebner's method, bromination under water, based on the Weber-Ditmar theory of vulcanization, is very unreliable in its present form. Until now only a way has been opened towards the development of methods to determine rubber directly.

S. P. THACHER: *On Mineral Compounds Used in Rubber.*

VICTOR HANZLIK: *A Few Notes on Rubber Goods Used in Beet Sugar Factories.*

FRANCIS R. PEABODY: *The Treatment of Crude Rubbers.*

DAVID BLOOM: *Does the Acidity of Crude Rubber Resin Indicate Its Botanical Origin?*

Rubber resins obtained by extraction with acetone, carefully dried and redissolved in warm alcohol, were titrated with standard alkali. The acidity of the resin (expressed as the number of cubic centimeters of alkali used) is referred to a standard quantity of the resin (one hundred milligrams) and this ratio is called the "acidity number."

In the course of the analyses of about one hundred and fifty varied samples of washed and unwashed crude rubbers, the acidity numbers of the resins seem to be a constant for all rubbers of the same class, regardless of their age or mechanical treatment.

Secretary

SOCIETIES AND ACADEMIES

THE CHICAGO SECTION OF THE AMERICAN MATHEMATICAL SOCIETY

THE twenty-ninth regular meeting of the Chicago Section of the American Mathematical Society was held at the University of Chicago on Friday and Saturday, December 29-30, 1911, extending through three half-day sessions. The total attendance was fifty-seven, including forty-three members of the society.

Professor L. E. Dickson, chairman of the section, presided at the opening session on Friday morning. Professor E. B. Van Vleck presided at the session on Friday afternoon while Professor Dickson was delivering his address on the "History of the representation of numbers as the sum of squares," and Professor E. J. Townsend presided at the session on Saturday morning.

At the business meeting on Saturday morning the following officers of the section for the year 1912 were elected: Professor D. R. Curtiss, chairman; H. E. Slaught, secretary, and A. L. Underhill, third member of the program committee.

On Friday noon the members lunched together at the Quadrangle Club, and in the evening they dined together at the same place and spent one of the most enjoyable social occasions in the history of the section.

The following papers were read at this meeting:

Professor Arnold Emch: "Involutoric circular transformations as a particular case of the Stein-erian transformation and their invariant net of cubics."

Dr. R. E. Root: "Iterated limits in general analysis."

Dr. Arnold Dresden: "Reduction of systems of linear differential equations of any order."

Dr. Louis Ingold: "Displacements in a function space."

Professor L. E. Dickson: "History of the representation of numbers as the sum of squares."

Professor F. R. Moulton: "Relations of families of periodic orbits in the restricted problem of three bodies."

Professor L. E. Dickson: "Note on Waring's theorem."

Professor L. E. Dickson: "Uniqueness of division in Cayley's algebras with eight units."

Professor J. B. Shaw: "On differential invariants."

Professor E. J. Wilczynski: "On some geometric questions connected with the problem of three bodies."

Professor Peter Field: "On Coulomb's laws of friction."

Dr. E. G. Bill: "Analytic curves in non-euclidean space."

Mr. H. F. Vandiver: "Theory of finite algebras."

Dr. Arnold Dresden: "Note on the second variation; Jacobi's equation and Jacobi's theorem in the calculus of variations."

Professor G. A. Miller: "Gauss's lemma and some related group theory."

Professor R. D. Carmichael: "On a class of linear functional equations."

Professor R. D. Carmichael: "On the theory of the gamma function."

Mr. Vandiver's paper was communicated to the society through Professor Dickson. In the absence of the authors, the papers of Mr. Vandiver, Dr. Bill, Professor Miller and Professor Carmichael were read by title.

The next meeting of the Chicago Section will be held at the University of Chicago, on Friday and Saturday, April 5 and 6, 1912.

H. E. SLAUGHT,
Secretary of the Section

THE BOTANICAL SOCIETY OF WASHINGTON

THE 78th regular meeting of the society was held at the Cosmos Club, Tuesday, February 6, 1912, at 8:00 P.M. President W. A. Orton presided. Thirty-seven members were present. Dr. H. W. Wollenweber and W. W. Ashe were elected to membership.

The following papers were read:

Conditions Favorable to Septoria lycopersici Speg.:
J. B. S. NORTON.

The author reported on a series of observations made on the development of *Septoria* under various conditions affecting growth.

The Relation of Soil Acidity to Plant Societies:
A. W. SAMPSON.

Since the day of Unger and Thurmann there has been considerable difference of opinion as to the relationship between soil chemistry and cover. The fact, however, that different soils support different plants is a matter of common observation. The bearing of soil acidity upon this point has been investigated by the author—chiefly in connection with range revegetation studies conducted in the Wallowa Mountains of northeastern Oregon.

The *Leguminosae* are commonly extremely sensitive to acid soils while many ericaceous species are rather closely confined to acid soils. For example, *Trifolium repens* fails in soils requiring for neutralization the relatively small amount, locally, of 5,000 pounds of lime per acre foot, while no species of *Vaccinium* is known that can be grown successfully in neutral or alkaline soils. Again, some genera (*e. g.*, *Populus* and *Rosa*) are apparently indifferent as regards soil preferences. The preeminent forage plant of the Wallowa Mountains, *Festuca viridula*, varies very widely in adaptability to acidity. The soils on which it grows luxuriantly vary in lime requirements from 5,000 to 41,000 pounds per acre foot. The four species of *Poa* and the two species of *Agropyron* occurring locally reach their best development on calcareous and neutral soils.

Notes of Travel in Central America: Professor A. S. HITCHCOCK.

Having visited the Canal Zone as members of the Smithsonian Biological Survey, Mr. Hitchcock and his son made a two months' side trip to Central America. Collections were made in Costa Rica at Port Limon, San José and Puntarenas, in Nicaragua at San Juan del Sur, Corinto, Masaya and Jinotepe, in Honduras at Amapala, in Salvador at La Union, Acajutla, Santa Ana and San Salvador, in Guatemala at Guatemala City, Volcanso Agua and Port Barrios. Mr. Hitchcock presented notes on the various incidents connected with travel in the countries mentioned and reviewed briefly the botanical results of the journey.

INVESTIGATIONS OF THE CARNEGIE INSTITUTION¹

THE past fiscal year has been, on the whole, the most fruitful year on record for the ten specially organized departments of research in the institution. Although some of these are not yet fully equipped, they are all so well organized and provided for that their energies may now be chiefly directed to the attainment of definite results.

A development of much interest in connection with these departments is that of cooperative effort coming through research associates and collaborators. The departmental facilities are already in considerable demand from capable investigators, and many of them are found desirous of using these facilities, not only to forward their own researches, but to collaborate in the researches proper of the departments. The favorable experience which has accrued in recent years in these matters indicates that it may be advantageous in the future to seek to secure an additional number of investigators who, by reason of their eminence, may collaborate effectively in this manner.

Each of these departments has now under way such a variety and complexity of work that it is difficult to summarize. Reference must be made, therefore, for matters of detail, to the reports of the directors of the departments, published in full in the current year book. Hence such allusions in the following paragraphs as are made to the progress of the year are necessarily brief and can deal only with the more salient

¹MEAN, intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹From the Report of the President, Dr. R. S. Woodward, for the year 1911.

aspects of departmental affairs and researches.

DEPARTMENT OF BOTANICAL RESEARCH

The activities of this department now necessarily cover a wide range, since any successful attempt to solve the problems of the origin, development, migration, and modification under varying climatic conditions of plant life must require extensive field observations, much laboratory experimentation, and increasing application of the sciences of chemistry and physics. It is natural and proper, therefore, that the staff and collaborators of the department should include many specialists, and that they should approach the problems to be investigated from many points of view. Thus it happens that the investigations of the past year have embraced, among others, studies of the evaporation, the increasing salinity, and the changes in vegetation following close after the receding shores of the Salton Sea; of the influences of temperature, rainfall, sunlight, soil-moisture, etc., on plant organisms; of the effects following transplantation from low to high altitudes and from arid to humid localities; of the variations in water and acid content of plants; of the chemical effects induced in plant tissue by light and heat; and of the physiological functions of leaves in plant life.

One of the most interesting investigations under way during the year is that of Dr. Ellsworth Huntington, research associate of the department, on the secular variations of climate of the southwest desert area in recent geologic time. From this work it is believed that some of the salient fluctuations in climate during the past two or three thousand years may be clearly made out. Another noteworthy investigation of the year is that of the respiration of cacti, undertaken by Professor H. M. Richards in

collaboration with the department. This has developed the remarkable fact of a definite diurnal periodicity in the acid content of the sap of the cacti under observation. The progress and status of many other instructive investigations are set forth at length under the twenty subdivisions of the director's report, to be found in full in the current year book. From this it appears that, in addition to the regular and associate members of the staff of the department, about an equal number of individual investigators have collaborated in the researches under way. Special attention may be here invited to the detailed account given in one of the subdivisions of this report by Professor Tower in reference to his further experiments on the evolution of chrysomelid beetles, the results of his early work in this line under the auspices of the institution having been issued as publication No. 48.

DEPARTMENT OF EXPERIMENTAL EVOLUTION

It is a well-known fact that important generalizations in science usually leave a multitude of details to be worked out. Indeed, advances often raise more questions than they settle. Such has been the wonderfully fruitful effect of the doctrine of evolution propounded by Darwin, Spencer, and Wallace a half century ago. It should not be surprising, therefore, that the program of the Department of Experimental Evolution presents a considerable variety of investigations related to the highly complex problem of heredity chosen by the director as the principal object of research. Thus the work of the year includes investigations of heredity in plants, insects, birds, animals, and man.

One of the most promising investigations of the year is that of the director in reference to the heredity of epileptics. Through his connection with the Eugenics Record Office, he has collaborated with Dr. David

F. Weeks, of the New Jersey State Village of Epileptics, and secured a large quantity of accurate statistical data bearing directly on this disorder. From these data it appears not improbable that important practical deductions may be presently, if not already, drawn. Another investigation continued during the year, which involves prime utilitarian application, is that of Dr. Shull on the effects of self-fertilization in maize, or Indian corn. His earlier conclusions, published in 1908, have been confirmed by the later studies. A striking result from the latter is that, other conditions being the same, the yield of cross-fertilized plants proved fifty per cent. greater than that of the self-fertilized plants. Observational and experimental work has been carried on also along many other lines. The total number of zoological individuals under study exceeded 2,000, while the range of plants observed included nearly 500 species and upwards of 40,000 individuals.

DEPARTMENT OF ECONOMICS AND SOCIOLOGY

The diversified work of this department has proceeded during the year in accordance with the plan approved by the executive committee in May, 1910, which contemplated completing the researches then under way as well as might prove practicable under the limitations of the balance of appropriations previously made to the department. A full statement of these appropriations, of the expenditures under them to date, and of the present available balance, will be found in the section of this report devoted to the proposed budget for the ensuing year.

As explained at length by the chairman of the department in his report, to be found in the current year book, progress in the work under way is necessarily slow, since

the heads of the divisions of research and most of their collaborators are primarily engaged in other occupations. But in spite of this handicap, inherent in the organization, much work has been accomplished, and the chairman reports that several of the heads of divisions are now engaged on their final reports.

DEPARTMENT OF HISTORICAL RESEARCH

The eighth annual report of this department, and the sixth of the present director, is an instructive record of effective progress along all lines of work thus far undertaken to discover and to render available the sources of American history. Members of the department have been engaged during the year searching the archives of Great Britain, France, Spain, and Mexico, as well as those of the United States, for all accessible data, and these are being rapidly put in form for publication in convenient manuals. Three such works have been published by the institution during the past year, namely, "Guide to the Materials for American History in Roman and other Italian Archives"; "Inventory of Unpublished Material for American Religious History in Protestant Church Archives and other Repositories"; and "Calendar of Papers in Washington Archives relating to the Territories of the United States." The following are now in press: "Guide to the Manuscript Material relating to American History in the German State Archives" and "Guide to Materials for the History of the United States in the Principal Archives of Mexico."

It is worthy of remark that the results of this department's activities have received very general commendation from professional historians in Europe as well as in America. The ten manuals thus far issued are already much in demand in foreign countries, and they seem destined to become

as important in aggregate usefulness abroad as at home. It is hoped that the institution may be thus enabled to render adequate acknowledgment for numerous courtesies extended to the department by officials of governments, archives, libraries, and other establishments.

GEOPHYSICAL LABORATORY

The signal success already attained by this laboratory leaves no reason for doubt as to the practicability of continued advances toward solution of that large and difficult group of chemical and physical problems presented by the materials of the earth's crust. The current report of the director reviews twenty-six papers which have been issued by members of the staff of the laboratory during the year. Among these papers is a noteworthy contribution to general physics, in which the scale of precise thermometry is extended by 1250° C. This extension was an essential incident to the studies of mineral fusion, crystallization, etc., carried on in the laboratory, but it is of equal importance to other branches of physical research. Another noteworthy paper is a preliminary contribution to the long-standing question of the constitution of Portland cement. The complexity of this substance proves to be far greater than hitherto supposed; but its general characteristics have been determined and the resources of the laboratory are adequate to complete the remaining quantitative details of the investigation.

International appreciation of the work of the institution is now shown in many ways. The merits of the researches of the geophysical laboratory have been more promptly recognized, indeed, than its projectors anticipated. Thus nearly all of the preliminary papers issued by members of the staff of the laboratory have been published in German as well as in English,

and arrangements have been made during the past year to have all such papers appear contemporaneously in both of these languages.

Of numerous investigations under way at the laboratory, attention may be called here to some preliminary studies of an active volcano, which indicate that the phenomena of vulcanism are within range of practicable determination and that progress in this direction is only a question of time and adequate effort.

DEPARTMENT OF MARINE BIOLOGY

In addition to the research work proper carried on by the director of this department during the year, much of his time and attention have been devoted to the construction of a new vessel and to the reconstruction of the laboratory at Dry Tortugas. Reference to this vessel, named the *Anton Dohrn*, has been made in a previous section of this report, and a description of her characteristics and equipment will be found in the current report of the director. It may suffice here, therefore, to state that this adjunct gives the department independent and adequate transportation facilities and greatly enlarged opportunities for marine research.

Mention was made in my report of a year ago of the probable damage done to the Tortugas laboratory by the destructive hurricane which swept the Florida Keys October 17, 1910. An inventory of the wreckage was made as soon as practicable, and it was found that an expenditure of \$4,000 would be essential to renew the establishment in a safe and effective manner. Accordingly, an allotment of this amount from the insurance fund of the institution was made by the executive committee at its meeting of November 17, 1910, and the wrecked buildings have been replaced during the past summer by struc-

tures at once more secure and more commodious.

On account of lack of quarters the director has been able to afford facilities for research at the laboratory to only eight investigators. Nevertheless, the year has proved fruitful in important advances. One of these, attained by Mr. G. H. Drew, of Cambridge University, relates to the rôle of certain bacteria in depriving surface sea water of nitrogen and in precipitating the vast deposits of chalky mud (oolite) of the Florida-Bahama region; another, by Dr. T. W. Vaughan, records definite progress in his quantitative determinations of the growth of corals and coral reefs; while the director and his collaborators have published twenty-one papers, mostly included in volumes Nos. 132 and 133 of the publications of the institution.

DEPARTMENT OF MERIDIAN ASTROMETRY

As already explained in a preceding section of this report, the meridian determinations of stellar positions at the temporary observatory at San Luis, Argentina, were finished in January, 1911. This completion in an unexpectedly short time of the more formidable part of the undertaking of the department in the southern hemisphere leaves only the minor task in photometry of measuring the magnitudes (or brightness) of those stars for which this property has not been hitherto measured. This task, requiring only two observers and light equipment, will be subject to small expense.

In the meantime the deductions of stellar positions and motions are proceeding expeditiously in the computing section of the department at the Dudley Observatory; so that the final catalogue, giving precise positions of all stars up to the seventh magnitude inclusive, may be expected to appear in due time. As often happens in such

extensive scientific investigations, many by-products are arising of hardly less importance than the primary ends in view. One of these, deduced from the director's preliminary Star Catalogue, published by the institution about two years ago, shows the mean velocities relative to the solar system of stars of different spectral types. The values derived from the "proper motions" of the catalogue are in striking agreement with those derived for the same stars by Professor W. W. Campbell from direct measurements of the motions of these stars in the line of sight. The remarkable result which is thus brought out from independent investigations is that the speed of a star through space increases with its age. Attention is here invited to the director's interesting summary of this by-product in his current report, the investigation in full having been published in the *Astronomical Journal*, April 3, 1911. It is of interest to note in this connection that the independent investigations of Campbell, referred to above, were also carried out by aid of grants made by the institution.

NUTRITION LABORATORY

Allusion has been made frequently in previous reports to a prime characteristic in the progress of all of the more highly developed sciences. This consists in the passage from the stage of observation and experiment to the stage of measurement and calculation, or in the transition from the stage of qualitative to that of quantitative knowledge. It is marked by the introduction of the meter, the balance, the thermometer, the telescope, the microscope, etc., and the definite methods of chemistry and physics. The development of the work of the nutrition laboratory affords a capital illustration of this characteristic mode of procedure, and therein we find also the best

justification for confidence in the enterprise.

The staff of the laboratory has been occupied during the year in the construction of new apparatus, in the improvement of apparatus already in use, in numerous researches on pathological and normal subjects, and in the preparation and publication of reports on results already attained. The year has shown also a remarkable increase of interest in the work of the establishment coming especially from members of the medical profession at home and abroad. Several of these have collaborated very effectively in the experiments under way, and the widely general approval of the objects and methods of the laboratory insures the heartiest cooperation from experts in the closely allied fields of physiological and pathological research.

The numerous investigations in progress and the publications issued during the year are reviewed in interesting detail in the director's report. Of the nine publications issued, one (No. 155 of the institution) gives the results of an important study of the variations of temperature in different parts of the human body. Of equal popular and technical interest also are the results, recorded in another paper, of experiments on men to determine the effects of breathing air rich in oxygen content.

THE SOLAR OBSERVATORY

By reason of the absence on leave of Professor Hale, the varied work of this observatory has been in general charge of Mr. Walter S. Adams, who, as acting director, has prepared the report of progress for the past fiscal year as well as that for the year 1909-1910. Quite fortunately the affairs of the observatory have proceeded without serious delay during Professor Hale's absence, and it is gratifying to announce that his health was so far restored as to permit

him to return to his duties October 1, 1911.

Although the construction and equipment of the observatory are still incomplete, the members of the staff are making rapid progress with their programs of solar, stellar, and physical observation and of computation and deduction. Thus the attainment of tangible results proceeds along with the development and installation of equipment. Attention is invited to a list of such results, attained during the year, cited in interesting detail by Mr. Adams in his report, but too long for an abstract in this place. It need only be said of them here that they justify expectations and that they increase confidence in the capacity of the establishment to advance astrophysical science.

The observatory has now, nearly fully equipped and in use, four highly effective telescopes: the Snow, horizontal, 30-inch reflector; the two tower-telescope refractors; and the 60-inch reflector mounted equatorially. The 150-foot tower telescope, together with its auxiliary apparatus, constitutes the most important addition of the year in the way of equipment. Varied use of the 60-inch equatorial proves it to be alike effective in visual, photographic, and spectroscopic work. It is especially penetrating in its capacity to reveal the characteristics of globular star clusters and spiral nebulae.

In view of the repeated failures of the contractors of St. Gobain, France, to cast a perfect disk for the 100-inch "Hooker telescope," it was determined to try the imperfect disk furnished by these contractors, but not accepted, four years ago. Accordingly an agreement was entered into with the makers to try shaping the disk, and to pay therefor in case it proves sufficiently stable after adequate trial. This work was begun early in the year, and good progress has already been made, although some delay

must result by reason of the illness of Professor Ritchey and his chief assistant in this delicate and laborious task. In the meantime the glass-founders of St. Gobian are unremitting in their efforts to secure a perfect disk.

It is with deep regret that the observatory and the institution are called upon to record the unexpected death, on May 24, 1911, of Mr. John Daggett Hooker, to whom the enterprise of the 100-inch telescope owes its inception. His intelligent interest in and appreciation of the work of the Mount a gift of \$50,000 in 1906 for the purchase of a disk and for the shaping of it for a 100-inch reflecting telescope. Unfortunately the difficulties in the way of casting so large a disk of glass, together with his untimely death, have prevented him from realizing his desire to see this telescope in use. But if the enterprise succeeds, as now seems quite hopefully probable, the observatory and the institution will be glad to link the constancy of his faith in scientific investigation to the constancy of the stars by means of diligent applications of the "Hooker telescope" to astronomical research.

DEPARTMENT OF TERRESTRIAL MAGNETISM

The magnetic survey of the globe undertaken by this department is proceeding effectively on both land and sea. Observations of the magnetic elements of declination, dip and intensity have been made at numerous points on the continents of Asia, Africa, Australia, Europe, South America and on the Polynesian Islands; while the non-magnetic ship *Carnegie* has secured a large quantity of data of immediate practical utility to navigation and of still greater importance, doubtless, in their relations to the general problem of terrestrial physics.

At the end of the previous fiscal year the

Carnegie was en route from the mouth of the Amazon to Rio de Janeiro. After visiting the ports of Rio de Janeiro, Montevideo, Buenos Aires and Cape Town, she arrived at Colombo, Ceylon, June 7, 1911. Having started on her present circumnavigation cruise June 20, 1910, her arrival at Colombo marked the end, approximately, of the first year out. During this year she traversed upwards of 23,000 nautical miles, measuring magnetic declinations at 252 different points, and dip and intensity at 172 different points at sea. In addition to this work, corresponding complete determinations were made on land at seven ports and intercomparisons of magnetic instruments were made at three ports.

Unexpectedly large errors have been found almost everywhere, except in the south Atlantic Ocean, in the best compass sailing charts now in use. This is especially the case in the Indian Ocean, for which some recently issued charts are in error as much as 4° to 6° in the "compass variations" assigned. To meet the pressing needs of mariners for more trustworthy charts, the data obtained by the *Carnegie* are promptly furnished to the hydrographic establishments of the world engaged in the publication of magnetic charts. It appears from the investigations of the department that the chief source of the errors in existing charts lies in a lack of knowledge of the secular variation of the magnetic elements. It is worthy of note, also, in this connection that observations of atmospheric electricity and atmospheric refraction have been carried on during this voyage of the *Carnegie*. The importance of precise navigation in recent times gives special interest to the outstanding uncertainties due to atmospheric refraction.

Expeditions for land determinations of magnetic data have been made to many

countries and to many islands. The most extended of these are that carried out by Mr. Stewart in traversing the length of the Amazon River and that by Mr. Sligh in Asia Minor, Turkey, Arabia, Greece, Tripoli, Tunis and Algeria. The director of the department, on his way to meet the *Carnegie* at Colombo, made observations at Tau Island, of the Samoan Group, on the day of the total solar eclipse, April 28, 1911; and also at six other island stations in the course of his voyage.

The office work of computation and compilation of results and of the construction and testing of instruments has proceeded simultaneously with the operations on land and sea. A complete collection of the data obtained since the establishment of the department, including those of the cruises of the *Galilee* and *Carnegie*, will be ready for publication by the end of the present calendar year. Three portable magnetometers have been completed and four others are under construction, while various improvements to instruments and apparatus in use have been made, along with all current repairs, in the construction and repair shop of the department.

INVESTIGATIONS OF RESEARCH ASSOCIATES

Between fifty and sixty research associates have carried on investigations under the auspices of the institution during the year, either by aid of grants made directly to them or for the purpose of publishing results of their investigations. Several of these associates have been connected with the departments of investigation. Many collaborators have also participated in the researches carried on under this head, and the fields of investigation are numerous and of very diverse kinds. An idea of the extent and variety of this work can be best gained by consulting the reports, in the current Year Book, of the individual investigators, by reference to the annual list

of publications of the institution and the general bibliography of the year. As indicating the diversity of these investigations, attention may be called to two remarkable publications in widely different fields. One of these is a treatise on dynamic meteorology and hydrography, by Professor V. Bjerknes, of the University of Christiania, and marks a noteworthy advance in this difficult branch of mathematical physics. Part I. of this work has been issued and Part II. is now in press. It is interesting to note, also, that permission has been given to a foreign publishing house to bring out an edition of this work in the German language. The other work referred to is entitled "The Polynesian Wanderings," by Mr. William Churchill. It attempts to trace the migrations of the Polynesians in the Pacific Ocean by means of a critical examination of the philological contents of their language. Mention may also be made in this connection of progress in the publication of the Classics of International Law, one work of which—namely, that of Richard Zouche—having been completed.

CHARLES X. DALTON

THE passing of Charles X. Dalton removes a personality familiar not only to a large circle of scientists throughout the country but to many of Boston's leading business men, with whom he had a large acquaintance owing to his association with that eminent optician, the late Robert B. Tolles.

Born in Philadelphia in 1840, Mr. Dalton learned his trade as an expert mechanician from a German instrument-maker of that city. In his early days he worked in the factory of Joseph Zentmeyer, the well-known microscope manufacturer, and during the Civil War, served as an army nurse. At the close of the war, he entered the employ of Tolles, and later (1867) was associated with him in the Boston Optical Works.

This enterprise, while never profitable financially, owing its existence for many years to the liberality and public spirit of a few wealthy citizens of this city, was epoch making for the industry, nevertheless; for the microscopes and small telescopes produced in its dingy shop attracted the attention of the whole scientific world and set standards not only for America, but Europe as well. To Mr. Dalton was entrusted the making of all the metal work which embodied the intricate designs of the great optician.

The freely spoken encomiums of the best instrument-makers of Europe attesting to the superiority of workmanship of the Tolles objectives have more than once made special mention of the excellence of their metal work. This Boston company was all too short lived, owing to the untimely death of Tolles in 1883, but many of Tolles's instruments, treasured to-day by connoisseurs as still unequalled, remain as fitting memorials of the genius of this master optician, and will also keep alive the memory of the clever mechanician whose deft workmanship contributed so much to their excellence.

For one or two decades preceding and immediately following the Civil War there was a widespread popular interest in the microscope among cultivated people as a form of amusement, although much serious scientific work was done likewise. Microscope clubs were common throughout the land, and in England as well. Many became experts in microscope technique and there was an active demand among the wealthier of these enthusiasts for the best instruments that could be produced, irrespective of cost. This stimulated the instrument-makers of England and America to use the utmost skill and best workmanship, and in the hands of famous opticians, among whom Tolles with his giant genius shone preeminent, the microscope was carried to a high degree of elaboration and efficiency. It was under such conditions that Charles Dalton was inspired to use his skill and cunning as an artificer of metals. Dalton was not a workman for wages only. He had that true love of his craft and a pride in his workman-

ship which characterized the true craftsman and which is vital for best results. He would never do mediocre work and was his own severest critic of his product. He made many of his tools and appliances and accomplished much by primitive but cunning methods which are a lost art to the mechanician of to-day, or made possible only by the use of elaborate tools.

The death of Tolles practically ended the work of the Boston Optical Co. A few instruments designed by Tolles were completed by his workmen, but no successor could be found to give adequate expression to the original genius of the master. For many years Mr. Dalton has carried on the business in the old Hanover Street building, making repairs on the Tolles instruments which have been sent to him as the only one competent to make them and doing a general business in the sale and repairs of optical and other delicate instruments.

The wane in popular interest in the microscope as a recreation for the dilettante and the cheap compact "continental" instrument, of high optical efficiency but reduced to the simplest terms as to finish and accessories, in short a laboratory tool designed solely for the special work at hand has become common in our schools and colleges. Such instruments of good quality are now turned out by the thousands by the great manufacturers, using labor-saving machinery and modern systems of divided labor, and a good microscope is cheaper to-day than formerly. The elaborate instruments of Tolles and other great opticians of the past generation, instruments in which cost was subordinated to every detail which added to convenience and efficiency, masterpieces of ingenious and perfect workmanship, are no longer made, and with them is disappearing the old-time workman whose knowledge and craft partook almost of the dignity of a profession.

No doubt this condition is quite in accord with modern ideas and economics, but there may be some who view the changing times with some regret, some who have known the spirit and moral fiber of the old craftsman

and rejoiced in the fruits of his workmanship. May be there are some who still feel that there is a dignity and fitness in studying the beautiful in science for its own sake even by the untrained, and take the microscope as more than a laboratory tool.

The originality and workmanship of these old instrument-makers are still felt and long will be felt in the industry. European microscopes which till comparatively recently have been of the most primitive types, are gradually changing in design by adoption of many of the original optical and instrumental features of Tolles and his contemporaries, bearing witness to the permanence and soundness of their work.

Mr. Dalton in his later years made most of the repairs on the microscopes and chemical balances of the Harvard Medical School, Massachusetts Institute of Technology, Wellesley College, and in fact of most of the educational institutions in and about the city, his work in this line occasionally taking him as far as Vassar.

Through this business, he had a wide circle of acquaintances and will be missed by many who have looked with pleasure on the coming of the genial little gentleman who with his clear complexion and bright eye looked seventy years young, a man whose scrupulous cleanliness of person but exemplified his own blameless character, a normal man and the highest type of American craftsman.

GEO. W. ROLFE

THE SECOND INTERNATIONAL CONGRESS OF ENTOMOLOGY

THE first International Congress of Entomology, held in Brussels on August 1-6, 1910, was an unqualified success. It was well supported by entomologists of all countries, both theoretical and practical, and also by many governments and institutions, which are at last beginning to realize the profound importance of this science in medicine and in agriculture. The membership was nearly 400, and upwards of 300 actually attended the proceedings. The results of the deliberations are being published in two volumes, the first being

devoted to the proceedings and discussions, the second to the numerous memoirs contributed by many authorities upon a great variety of subjects, including papers devoted to pure and to economic entomology. The volume of memoirs (515 pages, 27 plates) is now published and issued to members. The volume of proceedings will follow shortly.

It was decided at the first congress that the second congress should be held in 1912, and the following meetings every three years from that date, so that in future the International Congress of Entomology will be held one year before the International Congress of Zoology. The second congress will therefore be held at Oxford on August 5 to 10, 1912, under the presidency of Professor E. B. Poulton, D.Sc., F.R.S. A reception committee has been formed, consisting of:

Dr. F. A. Dixey, F.R.S. (Chairman).

Professor G. C. Bourne, F.R.S. (Professor of Zoology).

Professor H. L. Bowman, D.Sc. (Secretary to the Delegates of the University Museum).

Professor E. B. Poulton, D.Sc., F.R.S. (President of the Second Congress).

Geoffrey W. Smith, M.A. (Fellow of New College).

Commander J. J. Walker, M.A. (Secretary of the Entomological Society of London).

H. Eltringham, M.A. (Cant.), M.A. (Oxon.), and G. H. Grosvenor, M.A. (Secretaries).

It is hoped that the reception committee will be able to arrange for members of the congress to have rooms in the colleges at a moderate price, but this privilege will be available for gentlemen only. In order to facilitate the arrangements, it is requested that ladies and gentlemen who propose to join and attend the Congress send in their names as early as possible to the general secretary of the executive committee, who will be happy to give any further information. Ordinary members who pay £1 (25 francs) will receive all publications of the congress. Ladies and children accompanying members will, on payment of 10s. (frs. 12.50) each, have all privileges of members except that of receiving the publications. Life members who pay a com-

position of at least £10 (frs. 250), will receive free all future publications of the congress. The funds received in respect of Life Compositions will be invested, and only the interest will be at the disposal of the executive committee. Sir Daniel Morris, D.Sc., and the Hon. N. Charles Rothschild, M.A., F.E.S., have kindly consented to act as trustees of the funds. Members who propose joining the congress, or presenting papers, are requested to address the general secretary of the executive committee, Malcolm Burr, D.Sc., care of Entomological Society of London, 11 Chandos Street, Cavendish Square, London, W.

ANTARCTIC EXPLORATIONS

As every one knows from the daily press the Norwegian explorer, Captain Roald Amundsen, who made the first northwest passage ever accomplished by ship, has added to his laurels by reaching the South Pole. He verifies Shackleton's report that the pole is on an ice-capped plateau more than ten thousand feet above the ocean. Amundsen also discovered ranges of mountains, the peninsularity of King Edward VII. Land, and the origin of the oceanic ice-cap, known as Ross's Barrier. As soon as information as to the extent of the scientific work is received it will receive proper notice from SCIENCE.

Of the highest importance to the standing of American antarctic explorers is the information that the Australian antarctic expedition, in the ship *Aurora*, has verified in a general manner the accuracy of the discoveries of Captain Charles Wilkes, U. S. Navy, in 1840, of the Antarctic Continent. The leader of this expedition was Dr. Douglas Mawson, well-known to the readers of SCIENCE through his location of the South Magnetic Pole, in 72° 24' S., 155° 16' E. (SCIENCE, May 10, 1910). Dr. Mawson landed, February 19, on the glaciers of Adelie Land, with a party that remains there during the Antarctic winter. Another party under Dr. White is pursuing its scientific work at Termination Land, where it landed January 18. It is hoped that this confirmation of the reliability of Ameri-

can work will be set clearly before the American people as soon as details are obtainable.

SCIENTIFIC NOTES AND NEWS

REAR ADMIRAL GEORGE WALLACE MELVILLE, U.S.N., retired, known for his Arctic explorations and eminent as a mechanical engineer, formerly engineer in chief of the U. S. Navy, died on March 18, aged seventy-one years.

DR. W. H. WILEY has resigned the position of chief of the Bureau of Chemistry of the Department of Agriculture, which he has held since 1883.

AMONG the degrees conferred, on the occasion of the exercises commemorating the one hundred and twenty-fifth anniversary of the University of Pittsburgh, were the following on men of science: The doctorate of laws on Edgar F. Smith, provost of the University of Pennsylvania; N. L. Britton, director of the New York Botanical Garden, and L. O. Howard, chief of the Bureau of Entomology and permanent secretary of the American Association for the Advancement of Science. The doctorate of science on Ira N. Hollis, professor of engineering at Harvard University; C. F. Scott, professor of electrical engineering at Yale University; H. D. Campbell, dean of Washington and Lee University; A. D. Mead, professor of comparative anatomy at Brown University; C. M. Snelling, dean of the University of Georgia; R. K. Duncan, director of the department of industrial research of the University of Pittsburgh; James Ewing, professor of pathology at the Cornell University Medical School, and Milton J. Greenman, director of the Wistar Institute of Anatomy.

THE Smithsonian Institution was represented at the centennial celebration of the founding of the Academy of Natural Sciences of Philadelphia this week by Dr. Charles D. Walcott, Dr. Richard Rathbun, Dr. Frederick W. True and Dr. Theodore Gill. Dr. Leonhard Stejneger represented the U. S. National Museum, and Mr. F. W. Hodge the Bureau of American Ethnology on this occasion.

A PORTRAIT of Dr. James Tyson, emeritus professor of medicine, painted by Mr. Hugh H. Breckenridge, has been presented to the University of Pennsylvania.

DR. WILHELM WUNDT, professor of philosophy at Leipzig, has been made a knight of the Prussian order "pour le mérite."

LIEUT.-COLONEL D. PRAIN, F.R.S., director of the Royal Botanic Gardens at Kew, has been elected a foreign member of the Royal Swedish Academy of Sciences, to fill the vacancy left by the death of Sir Joseph Hooker.

DR. R. RUEDEMANN, assistant state paleontologist of New York, has been elected a member of the Academy of Sciences at Halle.

M. LOUIS DE LAUNAY, professor of applied geology in the Paris School of Mines, has been elected a member of the Paris Academy of Sciences.

DR. KRÜMMEL, professor of geography at Marburg, has been elected an honorary member of the Geological Society of Frankfurt.

DR. THEO. B. COMSTOCK has resigned as secretary and chief engineer of the Board of Public Utilities of Los Angeles.

At the end of the current year Professor Frank Fanning Jewett will retire under the Carnegie Foundation from the headship of the department of chemistry of Oberlin College after thirty-two years of active service. Professor Jewett received the A.B. from Yale in 1870, followed by the A.M. in 1873. He then studied at Göttingen and the University of Berlin. His first teaching appointment was that of assistant to Dr. Wolcott Gibbs at Harvard in 1876. The next four years were spent as professor of chemistry in the Imperial University of Tokyo, Japan. He was then called to head the department at Oberlin.

THE eight men who have influenced Wisconsin agriculture most are in the order named: Professor W. A. Henry, Professor Stephen M. Babcock, ex-Governor W. D. Hoard, Hiram Smith, Professor R. A. Moore, Dean H. L. Russell, Professor F. H. King and George McKerrow, according to the articles

submitted by students of agricultural journalism in the University of Wisconsin.

MR. F. G. FIGG, formerly first assistant at the Colonial Observatory, Hongkong, has been appointed director of the Mauritius Observatory.

PROFESSOR AUG. CRAMER, of Göttingen, has been appointed the successor of Professor Ziehen, as director of the psychiatric clinic of the University of Berlin.

DR. FINGERLING, of the Agricultural School at Hohenheim, has been elected director of the Agricultural Experiment Station at Möckern.

MR. SELSKAR M. GUNN, assistant professor in the department of biology and public health of the Massachusetts Institute of Technology, has become the editor of the *Journal* of the American Public Health Association, succeeding Dr. Burt R. Rickards.

DR. WALTER S. TOWER, of the University of Chicago, sailed from New York, on March 20, for South America, where he intends to spend six months studying the economic geography of Argentina, Chile and southern Brazil.

At the summer session of the Venice Marine Biological Station of the University of Southern California from June 24 to August 2, Professor Charles L. Edwards will give a course of lectures upon marine biology and direct the work in the laboratory and upon the motor sloop *Anton Dohrn*.

DR. WILDER D. BANCROFT, professor of physical chemistry at Cornell University, lectured before the Columbia University Biochemical Association on March 15. His subject was "The Study of Environment."

At the annual meeting of the Columbia Chapter of Sigma Xi, Professor Wm. J. Gies, gave an address on the chemistry of digestion.

PROFESSOR W. K. HATT, of Purdue University, delivered an exchange lecture before the students and faculty of the College of Engineering of the University of Illinois, March 6, on "Timber Preservation." He also gave an address before the freshmen of the College on "Mountain Railways."

BEFORE the Chemical Society, London, on February 29, Sir William Ramsay delivered a memorial lecture in honor of Henri Moissan, the eminent French chemist who died five years ago.

THE death is announced of Dr. Dittmar Finkler, professor of hygiene at Bonn; of Dr. Richard von Stoffela, professor of medicine at Vienna; of Professor Richard Andree, the geographer of Brunswick, and of Dr. A. Grünhegen, professor of medical physics at Königsberg.

MR. JAMES J. HILL has announced that he will build and maintain in St. Paul a reference library to cost not less than \$350,000.

THE *Medical Record* states that at the fourth annual meeting of the national committee for mental hygiene, held in New York, on February 17, a campaign was inaugurated which has as its object the improvement of conditions affecting the mentally afflicted. An anonymous gift of \$50,000 enables the committee to start the work without delay. Dr. William L. Russell, superintendent of Bloomingdale Hospital, was appointed chairman of a subcommittee which will survey the national field, under the personal leadership of Dr. Thomas W. Salmon, of the United States Public Health and Marine Hospital Service, who has been granted leave of absence for this purpose. Dr. Llewellys F. Barker, of Johns Hopkins University, was elected president of the committee.

At a meeting held on Tuesday evening, February 20, the Minnesota Pathological Society was formed, with nearly fifty charter members present. The following officers were elected:

President, Dr. A. S. Hamilton.

Vice-president, Dr. J. S. Gillfillan.

Secretary, Dr. H. E. Robertson.

Treasurer, Dr. J. F. Corbett.

Censors, Drs. F. L. Adair, R. H. Mullin and H. A. Tomlinson.

THE American Scenic and Historic Preservation Society takes pleasure in announcing that it has been accorded by the United

States Department of the Interior the honor of exhibiting for the first time a collection of pictures of National Parks, made by the Interior Department for the purpose of illustrating the work of the federal government in the protection of regions of great landscape beauty and natural phenomena. By the courtesy of the National Arts Club of New York, the pictures will be hung in its galleries at No. 15 Gramercy Park, and will be on exhibition under the auspices of this society from Wednesday, March 13, until and including Saturday, March 30. During this period the public will be admitted without cards on week days, from 10 A.M. until 6 P.M. After this exhibition the pictures will be sent on a tour for similar display in different parts of the United States.

THE statement appearing in the issue of *SCIENCE* of February 2, on page 197, regarding the passage of a resolution by the American Economic Association in favor of an International Commission on the Cost of Living, was inaccurate. At a round table discussion led by Professor Fisher the persons present voted unanimously in favor of such a commission, but owing to a provision in its constitution providing that the Economic Association will not commit its members to any position on practical economic questions, no formal resolution was passed.

THERE will be a U. S. Civil Service examination on March 30, for the position of dairy chemist, in the Bureau of Animal Industry, at a salary of \$1,800.

AN astronomical bulletin from the Harvard College Observatory states that seven excellent photographs of the spectrum of Nova Geminorum No. 2 were taken at Harvard on March 13 and the same number on March 14. A marked change occurred in the spectrum, the photographs on the first date showing only dark lines while the hydrogen lines $H\beta$, $H\gamma$, $H\delta$ and $H\epsilon$ have well marked bright lines on the edge of greater wave length, on the second date. Those last photographs closely resemble those of Nova Persei No. 2, on Feb-

ruary 24, 1901. The bright lines seen with the slit spectroscope at Ann Arbor may have been too narrow on March 13, to show with an objective prism. The brightness of the star has increased, and was about 3.5 magn. on March 14.

DOLFLEIN'S excellent "*Lehrbuch der Protozoenkunde*," the most complete of modern works of its kind, met with such immediate success that scarcely a year had elapsed before he began a third edition. The preface of this edition is dated September 3, and the book, published by Fischer, has been on the market for two or three months. So rapid has been the advance of protozoology, that not a chapter has escaped revision, or rearrangement with additions, the net result being an increase in number of pages from 914 to 1,043. In addition to the many new species introduced there is a new chapter on species, variation and inheritance. The author's attitude on special problems has not been changed and the parasitic forms, as before, receive the bulk of attention.

A MEETING of the members of the Central Branch of the American Society of Zoologists will be held at the University of Illinois, Urbana, Illinois, in the new Natural History Building, on April 4, 5 and 6. Thirty-five members have expressed their intention to be present at this meeting, but it is expected that a large number will be able to attend. The meeting will begin with a smoker at the University Club, on April 4, when President Edmund James will address the society. The formal program will begin on Friday morning at 9:30, with an afternoon program at 2. Professor George Lefevre will deliver the presidential address at the banquet at the University Club on Friday evening. The Saturday morning program will begin at 9:30. There will also be an afternoon program, if it seems necessary. Members of the society who expect to present papers should send titles to the secretary, Professor H. V. Neal, Knox College, Galesburg, Ills., not later than March 21. The printed programs will be sent out about the twenty-fifth inst.

THE Tennessee Academy of Science was organized at a meeting held in Nashville recently. A constitution was adopted and steps taken to hold an initial meeting in April. At this meeting in addition to a regular program the officers of the academy will be elected and steps taken to extend the membership so as to include all white persons in the state who are interested in any phase of science or cognate subjects. Meetings are to be held annually on the Friday following Thanksgiving. For the present the movement centers in the office of the state geologist at Nashville.

THE Cooper Ornithological Club, an organization of western bird students, has recently established two permanent committees for the conservation of wild life. The chief objects of the club in doing this may be stated as follows: (1) To cooperate with other organizations, including the State Fish and Game Commissions and the Federal Bureau of Biological Survey, to the end that the wild life yet remaining in state and nation may be more effectively protected. (2) To work at all times for an enlightened public sentiment along lines of the conservation of wild animals. Following is the personnel of the committees. For the northern division of the club, W. P. Taylor, Museum of Vertebrate Zoology, Berkeley, *chairman*; H. C. Bryant, University of California; J. S. Hunter, State Fish and Game Commission, San Francisco; H. W. Carriger, San Francisco, and John W. Mailliard, San Francisco. For the southern division, Frank S. Daggett, director Museum of Science, Arts and History, Los Angeles, *chairman*; J. Eugene Law, Hollywood; H. J. Lelande, Los Angeles; Howard Robertson, Los Angeles, and G. Willett, Los Angeles.

A SERIES of seven lectures on "Public Health" subjects are in progress at the University of Illinois. These lectures, given on Wednesdays and Fridays, beginning March 13, are as follows: "Sociological Aspects of Public Health," by Dr. Henry B. Favill, of Rush Medical College, Chicago; "Influence of Water Supplies on Public Health," by Professor Edward Bartow, University of Illinois;

"How Not to Be Sick," by Dr. John N. Hurty, secretary of the Indiana Board of Health. "Bovine Tuberculosis and Its Relation to Public Health," by Dr. Mazyck Porcher Ravennel, professor of bacteriology at the University of Wisconsin; "The Influence of Disease on Civilization," by Dr. Victor C. Vaughan, dean of the department of medicine, University of Michigan; "Ventilation of Schoolrooms and Bedrooms," by Dr. William A. Evans, of the *Chicago Tribune*; "Milk," also by Dr. William A. Evans.

ABOUT forty students of the University of Illinois, pursuing courses in Railway Engineering or Railway Administration, have joined in forming the Railway Club of the University of Illinois. The object of the club is to provide for informal meetings for a discussion of railway problems and to promote good fellowship among its members. The officers for the present semester are: H. E. Marquette, president; A. C. Van Zandt, vice-president; W. C. Sadler, secretary; A. S. Nevins, treasurer; E. L. Tinzmann, sergeant-at-arms.

A NEW map of the state of Illinois on a scale of approximately eight miles to the inch is ready for distribution by the State Geological Survey. It is prepared in three colors so as to represent drainage features in blue; railroads, land lines, towns, etc., in black, and county boundaries and figures showing altitudes above sea level for various towns in red. This map eliminates the errors of early land surveys, so that places are now shown with correct latitude and longitude. Railroad alignments are all highly accurate.

UNIVERSITY AND EDUCATIONAL NEWS

THE Massachusetts Institute of Technology has received from a donor whose name for the present is anonymous, a gift of two and a half million dollars for the erection of the buildings on its new site.

ACCORDING to the *Boston Transcript*, Harvard University has received subscriptions amounting to \$1,200,000 for the erection of freshmen dormitories.

MT. HOLYOKE College has received an anonymous gift of \$50,000 for the endowment fund which now amounts to about \$370,000.

THE University of Toronto has received from Mrs. William Freeland the gift of an endowment for a fellowship in anatomy in memory of her father, the late Dr. James H. Richardson, who for many years was professor of anatomy in the Toronto School of Medicine and the University of Toronto. The fellowship is to be known as the James H. Richardson research fellowship in anatomy, and is of the value of \$500. It is open to graduates of recognized universities and medical colleges, and to students of the University of Toronto who have completed the third year of the medical course in that institution. The holder of the fellowship will be required to devote his entire time during the tenure of the fellowship to investigation in anatomy under the direction of the professor of anatomy in the University of Toronto.

THE New York School of Applied Design for Women has received a bequest of ten thousand dollars by the will of Miss Cora F. Barnes. Also a Scholarship in Perpetuity, of one thousand dollars from Miss Catherine A. Bliss.

It should have been stated in SCIENCE last week that Dr. Horace David Arnold had been appointed dean of the Graduate School of Medicine of Harvard University, not of the Harvard Medical School. The graduate school of medicine is a new department of the university, being a part of the faculty of medicine. It should also have been stated that Dr. Edward Hickling Bradford would retire from the chair of orthopedic surgery and become professor emeritus.

THE Bryn Mawr European fellowship awarded to the student receiving the highest grade has been given this year to Miss Nora Cam, who has specialized in mathematics and physics. The president's European fellowship has been awarded to Miss Bernette Lois Gibbons, a student of chemistry.

CHAS. H. TAYLOR, professor of mineralogy at the University of Oklahoma, has been pro-

moted to the head of the department of geology. At the same meeting Mr. Irving Perrine, instructor in geology at Cornell University, was appointed associate professor of geology.

DR. PERCY E. RAYMOND, formerly of the Carnegie Museum, Pittsburgh, and more recently paleontologist to the Geological Survey of Canada, has been appointed assistant professor of paleontology at Harvard University, and curator of invertebrate paleontology in the Museum of Comparative Zoology.

DISCUSSION AND CORRESPONDENCE

NUMBER OF STUDENTS PER TEACHER

TO THE EDITOR OF SCIENCE: In the January 26 number of SCIENCE is a note on the "Number of Students per Teacher," by Professor A. S. Hathaway, in which he says:

It appears to me that the only correct way to determine the average number of students handled per teacher in any school is to divide the number of student hours per week by the number of teacher hours per week.

This formula might simplify the *mere* mathematics of the situation, but it would most certainly fail to give just the information desired—the strength of the teaching force in an institution, or, in the words of Professor Hathaway, "the average number of students handled per teacher." It is then far from being a correct way, to say nothing of the *only* correct way.

The following illustration will show how the method suggested would miss the very purpose of our calculations. Suppose that a college of 300 students, averaging 15 hours recitation per week each, has 5 instructors, each teaching 20 hours per week; then the result would be, according to the formula suggested,

$$300 \times 15 \div 5 \times 20 = 45 \text{ "students handled per teacher."}$$

Now, another college with the same number of students, each reciting also on the average 15 hours per week, but with 10 teachers, each meeting classes 10 hours per week, would

show the same result; or a college of 225 students, averaging 20 recitations per week, with 10 teachers, each having 10 classes per week, would show 45 "students handled per teacher." Certainly the teaching forces of these schools would not be equally strong.

It is not particularly the average number of students per class, or recitation, that we are after. Even if this were our object we should find the matter more complicated than Professor Hathaway has supposed. Some "courses" require a proportionately larger number of recitations per hour's credit than others. And how should we treat laboratory work, which can not with fairness be classed with recitations? Some laboratory courses require very little outside work, but more work in the laboratory, while others require a considerable amount. What complicates the matter still more, is the fact that in many cases student assistants direct such courses in large part while in others professors attend to the work themselves. These are only a few of the complications one actually finds.

The class work does not afford the only opportunity for the teacher to assist and stimulate the student; and any scheme based upon class work alone would not only do an injustice to some of the very best of our educational institutions, but would also tend to emphasize unduly a practise that is doubtless already carried too far.

JOSEPH PETERSON

UNIVERSITY OF UTAH,
SALT LAKE CITY

ARE TEACHERS ENTITLED TO COMPLIMENTARY DESK COPIES OF TECHNICAL BOOKS?

HERE is the teacher's point of view:

The texts which I am using are of no personal benefit to me. I am supposed to use the latest edition, and to change the text once in a while. I do not see how I can well afford to buy them. The publishers get big profits out of the students and can well afford to give a copy to the teacher, while, on the other hand, the teachers' salaries are meager. And as to new reference books and practical engineering books, I can not always order them

for the college library without first seeing the book. So the only way left me is to ask publishers for a desk copy, however humiliating this may be.

Here is the publishers' point of view:

We consider it a good business policy to send a desk copy to the professor in charge of a course where a considerable number of our books are used. We also send copies of new books to professors prominent in their respective fields, hoping for returns on account of their recommendation. But the privilege of free books is greatly abused by some teachers, who finally succeed in accumulating fair-sized libraries of free books. Again, frequently we get requests for desk copies not only from the professor in charge, but also from all the instructors who assist him in his classes. Moreover, these requests come from the same schools year after year, showing that the instructors are allowed to appropriate the books. This we consider an unnecessary and unjust burden upon the retail price of technical books. At the same time we hesitate to refuse such requests, for obvious reasons. One of the worst features of the situation is that requests for desk copies come from colleges from which only two or three copies are ordered later on.

Here is the writer's point of view:

The question raised is one of equity and justice to both the teachers and the publishers. Moreover, the dignity of colleges of engineering is to be considered. Since this is a matter of ethics, equally applicable to practically all engineering colleges, it ought to be decided by the Society for the Promotion of Engineering Education. Other national engineering societies have committees on professional ethics, and this is evidently a problem for such a committee. A resolution approved by the society will have a great moral effect with both teachers and publishers, and would be an important step towards the solution of this vexed problem.

I feel rather strongly that all requests for free copies of books should be pronounced unprofessional and undignified. If a teacher does not care or can not afford to buy a book,

the college ought to buy a copy and place it at his disposal as long as he needs it in his teaching, the book remaining the college property. The college provides the teacher with an office and its furniture, heat, light, stationery, lantern slides, lecture apparatus, etc. To provide text-books when requested would be but a small additional expense, but it would mean a great deal for the teachers, and would put the whole matter upon a dignified business-like basis. As it is now, the situation reminds one of the railroad passes, now fortunately prohibited by law.

As to new engineering books, it is to the advantage of colleges, publishers and teachers that an opportunity should be given to those engaged in teaching to see and to inspect all noteworthy new books relating to their respective subjects. This end can be attained easily without sending out complimentary copies. The publishers of engineering books could arrange to move a few copies of new books along definite "circuits," each comprising several colleges. In each college it would be the duty of the dean or of the head of the respective department to bring the new book to the attention of the faculty and to consider the advisability of ordering a copy for the college library. There is nothing compulsory in this scheme; it would be a privilege offered by the publishers, and if certain teachers should not care to avail themselves of this advantage that would be their own business.

As stated before, in my opinion it would be to the best advantage of all concerned if a distribution of complimentary books were done away with altogether, except perhaps as voluntary and unsolicited gifts from authors and publishers to their friends. However, with the above scheme of "circuit books" even these gifts would become less and less necessary, because in most cases a person merely wishes to know that a certain book has been issued and also likes to know its scope and plan. After that, it mostly becomes a dead weight in his library.

Should the suggestions made above be deemed too radical in view of the established custom and the conditions of the trade, I

would suggest for the consideration of the Society for the Promotion of Engineering Education the following partial improvement in the method of requests for desk copies:

1. All requests for desk copies to be sent to the publishers only by the deans of colleges, and not directly by individual teachers or heads of departments. This would insure more justice, uniformity and dignity.

2. All free copies to remain the permanent property of the college, and not of individual teachers. This will reduce the number of requests to a reasonable amount.

3. Whenever possible, teachers and colleges ought to purchase books and avoid asking for complimentary copies.

CORNELL UNIVERSITY

SCIENTIFIC BOOKS

Melanesians and Polynesians; Their Life Histories Described and Compared. By GEORGE BROWN, D.D. London, MacMillan & Co. 1910. Pp. 451, 70 illustrations. Price, \$3.00.

The work is a comparative study of two groups of mankind generally supposed to have next to nothing in common. The relationship of these groups, however, has been maintained by some students since the epoch-making explorations of Wallace, who considered the Pacific peoples as variants of one race. Mr. Brown's theory, based principally on the languages concerned, in which he is an authority, is that a Negrito substratum formerly occupied the East Indies as far west as Borneo, also the continental skirts, and this stock became diluted by infusion of blood from India. Later the pressure of Malay tribes drove them out into the Pacific, the Polynesians having the greatest admixture of a light brown stock drifting to some point of radiation, perhaps Manua of the Samoan group, and the Melanesians, retaining more of the blood of the original black inhabitants, dispersed to the islands where they live at present. The Melanesians are thus regarded as the older, less commingled stock.

His long residence in New Britain and

Samoa and his command of the native languages fit Mr. Brown especially for the work and his opinions are entitled to great respect. The intention to establish by comparison the cultural affiliation of the dusky and fair-brown peoples has produced a most interesting and valuable body of observations charmingly presented in clear English, not only a contribution to science in the way of an almost unique comparative study, but a non-controversial book well worth reading for general information.

WALTER HOUGH

Herpetology of Missouri. By JULIUS HURTER, Sr., Curator, Academy of Science of St. Louis, Mo. Pp. 215; 12 pl. relating to structural characteristics.

There have been various *resumés* of the fauna of states, these publications of more or less economic value, but it is genuinely pleasing to note the appearance of the present work in which it is evident throughout that the author has devoted much labor and time in presenting a detailed and practical review. A publication like this stands as a fine example of what should be forthcoming from other workers on local fauna. Carefully systematized it also treats those economic features which greatly enlarge the field of usefulness. Too many of our local scientific workers devote a great amount of time and space to the treatment of synonyms, forgetting that this phase of their subject is of absolutely no interest to the great mass of readers, eagerly awaiting the zoological history of their home territory.

The farmer, the natural science teacher and the younger student will find Mr. Hurter's work of immediate and practical interest, while the technical descriptions are sufficiently elaborate to properly identify any of the species. There is a series of well-prepared plates relating to the mouth characters of salamanders and frogs, the foot characters of the latter, the scalation of serpents and like characters.

Looking through the systematic arrangement, one notes several apparently recent

changes in the nomenclature relating to families and genera. The author of the publication remarks that he has adhered strictly to the "International Rules of Zoological Nomenclature," adopted by the International Congress of Zoology. It seems a pity these adopted rules have been followed by the frequent discoveries that names familiar for the past quarter of a century and more, can no longer be permitted to stand. These never-ending changes and the constant growth of the list of synonyms bring about perplexing conditions, even to the technical worker. Some remedy might result, by accepting as a standard, a monumental world's work like Boulenger's "Catalogue of Reptiles of the British Museum." Time would, of course, elicit modifications, but with a standard agreed upon our technical workers would find more time for investigations along more original and generally valuable lines.

RAYMOND L. DITMARS

NEW YORK ZOOLOGICAL PARK

A REMARKABLE JOURNEY ACROSS THE SAHARA

ONE of the most daring journeys conceivable on the Sahara has recently been successfully accomplished by Count René le More who, almost alone, went from southern Algeria directly across the desert to Timbuctu. The journey of about 8,000 kilometers altogether, to Timbuctu and return, occupied about 13 months, of which three were passed in Timbuctu.

Leaving Ghardaia in November, 1910, le More reached Timbuctu in the last of April. He returned by nearly the same route. Discarding all precedents in Saharan travel, le More was accompanied by only two persons, a servant and an interpreter-guide, both of whom were Arabs. He had one Touareg riding camel and two small Algerian baggage camels, and carried the minimum amount of baggage, of which two or three American guns formed a prominent and a useful part.

No account of this journey has yet appeared, but in *Le Matin*, January 15, 1912,

there is an interview giving some of the main facts. The route taken in going was by Ghardaia, el Golea, In Salah, Tamanrauet, Kidal to Gan Gao, on the Niger River, thence by the river to Timbuctu. On the return a slightly different course was taken, passing somewhat to the west of Timanrauet, but retracing the previous way from In Salah.

The entire journey was perilous, not only because of the natural dangers attending desert travel, but especially on account of hostile tribes. Soon after le More left Ghardaia, I was told by an officer that the venturesome Frenchman would hardly be able to pass through the Touareg country with so small a company, the Touaregs would surely cut off his head. On the way le More went 29 days, going south from Timanrauet, without seeing any person outside of his own caravan. On the return the little company had exciting adventures in fighting off bands of robbers, coming off with better luck than other travelers through the region. Graves of several unfortunates were seen between Kidal and Gan Gao.

The purpose of the intrepid traveler was to study the country that he might later cross to Timbuctu by aeroplane. As a result he knows the best, or the only situation for relay stations, and much of the conditions attending desert travel, and he considers the project as possible of accomplishment. The result is that le More proposes to cross the desert again, but the next time in the air. Whether this difficult task is finally accomplished by le More remains to be seen, but there is little doubt that in the very near future aeroplanes will not be unknown in the extreme southern part of Algeria, since it is said that the French army in the colony has been actively engaged for several months in working out the details of an aeroplane corps with headquarters at Biskra.

Owing in large part to its relatively high elevation above the sea, the western Sahara is not so intensely arid as the eastern Sahara. In the vicinity of Ouargla and Ghardaia, for example, there is considerable vegetation, especially along the oueds. Le More's photo-

graphs show, also, that much further south, at In Salah and beyond, over half way to Timbuctu, there is a similar condition of affairs. It is probable, however, that the vegetation of the mesa-like areas, the *reg* or the *hamada*, may be barren in the extreme south, since even at Ghardaia there is very little vegetation on such areas. The mid-Saharan country is of the greatest interest botanically since there the Mediterranean element is almost wholly lacking, and the influence of the countries to the south of the desert begins to be felt. We shall await with much expectancy the promised detailed account of this remarkable journey.

DESERT LABORATORY

BOTANICAL NOTES

SUPPLEMENT TO ENGLER AND PRANTL'S ALGAE

THE volume of the "Pflanzenfamilien" containing the Algae (I., abt. 2) was completed fourteen years ago (1897), while most of the parts of which it was composed appeared several years earlier. In 1909 two supplementary Lieferungen were issued by Wille, in 1910 two more were issued by Wille, Kjellman and Svedelius, while two more were issued in 1911 by Svedelius. These have now been brought together by the Leipzig publisher, Wilhelm Engelmann, under the subtitle of "Nachtraege zum I Teil, 2, Abteilung." It covers the period from 1890 to 1910, and so brings the treatment of the Algae down to date.

The first thing one notices is the considerable modification of the schematic chart of the relationship of the families of the green algae. The five groups (classes) are developed from the Flagellata, the Protococcales being the primitive class with *Volvocaceae* as the lowest family. From the latter came the Conjugatae as a side line ending blindly. Above *Volvocaceae* are placed *Tetrasporaceae* which lead by one line through *Protococcaceae* to *Hydrogastraceae* and *Valoniaceae*, and by the other to *Ulvaceae*. The family *Valoniaceae* is regarded as the lowest of the class

Siphonocladales, which culminates in *Dasycladaceae* and *Sphaeropleaceae*. From *Valoniaceae* a line reaches *Bryopsidaceae* in Siphonales, culminating in *Vaucheriaceae*. The *Ulvaceae* are the lowest of the Chaetophorales, which pass by several lines to *Chroolepidiaceae*, *Coleochaetaceae* and *Oedogoniaceae* at the summits of as many genetic lines. A significant thing in the treatment of these families of green algae is the association of five families of colorless plants as "Nebenformen" related to *Volvocaceae*, *Pleurococcaceae*, *Protococcaceae*, *Oocystaceae*, and *Oedogoniaceae*, thus adding another step to the movement for the obliteration of the distinction between algae and fungi, and their assembling into new groups on morphological characters.

In passing it may be noted that *Pleurococcaceae* are separated from *Protococcaceae* by the absence of zoospores in the former and their presence in the latter, contrary to some recent algologists. Nor has the author been stampeded into dividing *Hydrogastraceae* and in his system *Protosiphon* and *Botrydium* lie peacefully side by side as related genera in the same family. *Characeae* are still so placed as to immediately follow Siphonales, and by this one is reminded of Wille's suggestion of their relationship in his earlier treatment. The revision of the Phaeophyceae was partly made by Kjellman, and on his death it was continued by Svedelius. It thus happens that some of the families are the joint work of the two authors, while in other cases Svedelius alone did all of the work, as in *Sphacelariaceae*, *Laminariaceae* and *Fucaceae*. The revision of the Rhodophyceae also is the work of Svedelius. Here the treatment is necessarily the same as that of Schmitz and Hauptfleisch fourteen to fifteen years earlier. However in the difficult family of the *Corallinaceae* the genera of the earlier treatment are freely broken up into smaller ones in accordance with the trend of recent opinion, resulting in the recognition of twenty-four genera instead of nine, with a considerable shifting of their places in the family.

NOTES

WITHIN the past two years Dr. W. C. Coker has rendered a distinct service to botany by the publication of two historical papers in the *Journal of the Elisha Mitchell Scientific Society*, the first (April, 1910) entitled "A Visit to the Grave of Thomas Walter" and the second (July, 1911) "The Garden of Andre Michaux." Walter's grave is now in the midst of a dense forest growth in southern South Carolina, not far from the swamps of the Santee River, although when he was buried his grave was made in what had been his botanical garden. The flat stone over the grave tells us that he died "in the beginning of the year 1788." No traces of the garden remain. An old oak at the head of the stone is now heavily draped with *Tillandsia*. Here he lies alone in the dense wild shade of his forest-covered garden.

Michaux's garden was about ten miles from Charleston, but like that of Walters has become overgrown with a heavy forest growth of mostly native species, but undoubtedly some of the trees date from Michaux's time, and were probably planted by him.

THE same writer's report on "Science Teaching in North Carolina" (*N. C. High School Bull.*, July, 1911) contains some good suggestions in spite of the statement that the committee "has been unable to arrive at any general agreement" as to what the science work should be. However they agreed in one most important conclusion, namely, that where single courses in science are offered they "should include the most important facts and principles" of the sciences concerned, and this is commended especially for "students whose instruction is concluded with the high school."

In the paper on "The Wilting Coefficient for Different Plants and its Indirect Determination" (U. S. Dept. Agric. Bureau of Plant Industry, Bull. 230) L. J. Briggs and H. L. Shantz attempt "to determine the extent of the variation exhibited by different plants with respect to the minimum point to which

they can reduce the moisture content of the soil before permanent wilting occurs," with the result that they conclude that the differences "are so small as to be of little practical utility from the standpoint of drought resistance." There is, however, a "great range in the wilting coefficient due to soil texture." The bulletin can not easily be summarized, and must be read by every botanist who is interested in physiological problems. The apparatus used is very ingeniously devised.

ALLIED to the foregoing is E. N. Transeau's paper on "Apparatus for the Study of Comparative Transpiration" in the July, 1911, number of the *Botanical Gazette*, in which he describes new forms of chronograph, weight droppers and irrigators, which he has devised and found useful.

Two recent ecological papers by R. M. Harper may be listed here, namely, "The River-bank Vegetation of the Lower Appalachicola, and a New Principle Illustrated Thereby" (*Torrey*, No. 11, 1911) and "The Relation of Climax Vegetation to Islands and Peninsulas" (*Bull. Torrey Bot. Club*, Dec., 1911).

AMONG recent economic papers are "The Propagation of Guayule by Seed," by Dr. J. E. Kirkwood (*Am. Review of Tropical Agriculture*, Vol. I.); "The Artificial Ripening of Persimmons," by Professor F. E. Lloyd (*Proc. Ala. State Hort. Society*, 1911); "American Medicinal Leaves and Herbs," by Alice Henkel (U. S. Dept. Agric. Bureau of Plant Industry, Bull. 219). The last named should interest the students in our schools of pharmacy.

THE "Annual Report of the Director of Forestry of the Philippine Islands" for the year ending June 30, 1911, contains much interesting matter for the botanist and general reader as well as for the professional forester. It is evident that there are serious forestry problems on the Islands not wholly unlike those that confront us in the United States, for the reckless destroyer is there just as he is here.

"The Forests of Oregon" (Bull. I., Oregon State Board of Forestry, 1911), by Professor G. W. Peavy, and the "First Annual Report of the State Forester" of Oregon (1912), by F. A. Elliott, indicate the state of mind of the people of the northwest in regard to the conservation of their forests.

ONE of the best of recent publications on trees is "New England Trees in Winter," by Professors Blakeslee and Jarvis, of the Storrs Agricultural Experiment Station (Bull. 69, 1911). After a helpful introduction, by means of keys the student is led to the principal genera, where further keys lead him to the species, and last to full descriptions accompanied by excellently selected photographs (in "half tone"). We do not recall any better treatment of our trees than is to be found in this publication, nor anything approaching it in other station bulletins. The authors are to be congratulated upon the quality of the matter which they have presented, and the Station upon its wisdom in giving it publication.

HERE may well be mentioned favorably E. R. Jackson's "Forestry in Nature Study" (U. S. Dept. Agric. Farmers' Bulletin, 468), which should be found in every public school in the country. Mr. Lamb's "Key to Common Kinds of Trees" (p. 38) should prove helpful to many teachers who have somewhat hazy ideas as to the identity of the trees about them.

THE UNIVERSITY OF NEBRASKA

SPECIAL ARTICLES

THE ACCUMULATION OF OIL AND GAS IN SANDSTONE

LET two plates of glass be slightly inclined to each other and touching along one edge. Place by means of a pipette some petroleum and water between the plates. By manipulation of the plates, cause a bubble of air and oil to be enclosed within the water. It will be noticed that while the oil surrounds the air, much more than half of the oil will lie toward the thinner end of the combined bubble. This would, of course, naturally follow, since liquids are subject to capillarity and gases not.

Let us now consider the newly formed strata of marine or lagoon shales and sandstones, which are potentially petroliferous. All the interstices will at first be filled with water. Assuming now that the petroleum and natural gas arise from chemical changes in included organic substances, principally in the shale, we have the following sequence of events. The gas that originates finds itself forced by the greater hold that the water has for the fine interstices to take a position in the largest near interstice. If this is more globular than tubular or flat, a bubble of gas will be thus imprisoned, otherwise it will move along till it reaches the largest lacuna. In other words, much of the gas will leave finer grained rocks for the coarser, and so produce an accumulation of gas in sandstone reservoirs. Gas then is the first constituent to be forced into these reservoirs.

But further, although petroleum has a lower capillarity constant, it has an extraordinary capacity of spreading along a surface between water and a gas. This is shown by the way oil will surround a bubble of air in water between two plates of glass. Therefore, in the movement of the gas bubble from the place of origin to the reservoir, each will carry with it a pellicle of oil, and thus accomplish an accompanying movement of oil from the place of origin to the reservoir.

I regret that I have not the facilities to demonstrate experimentally these principles, since they would be easily put to the test, given the required apparatus.

As to their practical bearings,

(a) Since the shale can contribute to a neighboring sandstone reservoir, contiguous bodies of organic shale and limestones would be considered favorable circumstances, rather than negligible as held by I. C. White, who finds the origin of the oil and gas within the sandstone.

(b) A reservoir may be expected to receive its oil and gas from shale above as well as below.

(c) A sandstone embedded within shales that seem to have very little oil in them may

yet have derived its oil from them in the past. The oil has been largely moved away as formed. Hence, richly petroliferous shales are not a necessary indication in oil prospecting.

(d) Gravitational sorting requires not only a certain necessary degree of dip, but also a necessary degree of porosity, because in interstices below a certain size, surface tension checks the motion necessary for gravitational sorting. For this reason, water-filled shales or very fine-grained sandstones or limestones lying above porous rocks, act as impervious barriers, instead of allowing the oil and gas to reach the surface.

(e) While gas can move in a water-saturated rock with a lower degree of dip or with a lower porosity than oil, yet, since the gas bubble carries with it a pellicle of oil, a certain quantity of oil can be carried where it would not otherwise move.

(f) Inasmuch as all porous reservoirs in the strata constituting our oil fields were originally water-filled, dry porous sands really contain gas. It is not recognized because not under sufficient pressure to escape noticeably. This gas has been contributed to it generally by neighboring strata, and may have served for the transport of oil. As gas becomes more expensive, this gas may be extracted by suction, as is already done in gas-sands which have lost their pressure.

Of course, the principles here proposed are not exclusive of the action of gravitation and moving water, but act in conjunction therewith.

ROSWELL H. JOHNSON

BARTLESVILLE, OKLAHOMA

THE AMERICAN SOCIETY OF ZOOLOGISTS

THE Eastern and Central Branches of the American Society of Zoologists met in joint session at Princeton University, Princeton, N. J., December 27 and 29, 1911, in conjunction with the American Society of Naturalists and the American Association of Anatomists.

The following officers of the Eastern Branch for the ensuing year were elected:

President—A. G. Mayer, Carnegie Institution of Washington, D. C.

Vice-president—G. A. Drew, Marine Biological Laboratory, Woods Hole, Mass.

Secretary-treasurer—John H. Gerould, Dartmouth College, Hanover, N. H.

Additional Member of the Executive Committee—H. E. Jordan, University of Virginia.

These officers, in addition to David H. Tennent and Ross G. Harrison, will constitute the executive committee of the Eastern Branch. It is understood that the same officers of the Central Branch that served last year will continue in office.

The following persons were elected members of the American Society of Zoologists:

Central Branch—J. Frank Daniel, University of California; T. W. Galloway, James Milliken University; Wilhelmine Enteman Key, Lombard College; George R. La Rue, University of Michigan; Joseph A. Long, University of California; Marian L. Shorey, Milwaukee-Downer College; Aaron F. Shull, University of Michigan; Leroy D. Swingle, Nebraska Wesleyan University.

Eastern Branch—Thomas Barbour, Harvard University; M. T. Burrows, Cornell University Medical College; H. S. Colton, University of Pennsylvania; E. D. Congdon, Cornell University Medical College; Henry Fox, Ursinus College; Leland Griggs, Dartmouth College; Mary J. Hogue, Mt. Holyoke College; M. H. Jacobs, University of Pennsylvania; H. G. Kribs, University of Pennsylvania; C. V. Merrill, New York University and Bellevue Hospital Medical College; H. D. Reed, Cornell University; A. H. Wright, Cornell University.

The following committee was appointed to consider during the ensuing year the problem of the organization of the society, and to prepare a new constitution: H. V. Wilson, chairman; E. G. Conklin, G. A. Drew and R. G. Harrison (Eastern Branch); F. R. Lillie, W. A. Locy and M. M. Metcalf (Central Branch).

The following papers were presented at the meeting, either in full or by title:

The Sense of Smell in Necturus maculatus: R. E. SHELDON, University of Pittsburgh.

Conjugation and its Significance in the Ciliate, Didinium: S. O. MAST, Johns Hopkins University.

Didinia about to conjugate decrease nearly three fourths in size, and the anterior ends become considerably flattened. They find each other by random movements, join anterior end to anterior end and remain together from four to twelve hours or longer, depending largely upon the tem-

perature. The nuclear changes are similar to those found in *Paramecium*. A large percentage of exconjugants usually die, but sometimes all live. The proportion of fatalities is essentially the same in small individuals taken from the same culture but not allowed to conjugate, while large individuals nearly all live. There is no evidence indicating that there is any difference in the vitality of the two individuals of conjugating pairs foreshadowing sexual differentiation, as held by some investigators. The rate of fission is apparently not affected by conjugation, and if there is a rhythm in the rate of division, such as has been described for certain other infusoria, it is independent of conjugation as is shown by the following results. In seven closely related families under the same environmental conditions the rate of fission was practically the same during a period of several weeks, although the number of generations since conjugation at the close of the experiment varied in the different families from 123 to 553. Conjugation is almost invariably accompanied by encystment, i. e., when certain individuals in a culture conjugate others encyst. This seems to indicate that conjugation, like encystment, functions in bridging over periods of unfavorable environmental conditions. Conjugation produces an increase in physiological variability; some of the exconjugants consequently have a better chance to survive under adverse conditions than do those which have not conjugated.

Behavior of Fire-flies (Photinus ardens) with special Reference to the Problem of Orientation: S. O. MAST, Johns Hopkins University.

The fire-flies studied are found in dark crevices or under ground during the day. In the evening when it is still light enough to read they come out; the females crawl to the tips of grass or other objects and remain quiet; the males fly about and glow fairly regularly at intervals of about five seconds. The females do not glow unless light from the males or from some other source is flashed on them. When a female glows in response to the glow of a male, the male ordinarily turns directly toward her. This is repeated until the two come together, after which copulation takes place. There are no other factors involved in mating. If a female is held near a male he pays no attention to her unless there is actual contact, showing that neither objective vision nor smell is functional in mating. The males do not orient when exposed to continuous illumination. They respond only to flashes of light, and do not

react until after the light has disappeared. Thus orientation may take place in total darkness, and it is surprising how accurately these animals turn through the proper angle in the total absence of the stimulating agent that caused the response. Here we have a case in which it is clearly demonstrated that light does not act continuously in the process of orientation as demanded by Loeb's theories, a case in which it is also clearly demonstrated that continuous stimulation is not necessary to keep the organism oriented.

Experiments with the Influence of Darkness upon Pigment Development in Amphibian Larvæ: A. M. BANTA, Station for Experimental Evolution.

From newly laid eggs series of *Ambystoma tigrinum* were reared (1) in darkness and (2) in ordinary laboratory light, and compared with those developing (3) in the pool where the eggs were laid. The amount of pigment developed in each individual of the different series was determined by means of color tops, and records were made in terms of the percentages of black, white, orange and yellow, which when blended matched the color of the animal's skin. For the salamanders on the average the body color of the series reared in darkness contained 49.7 per cent. black and 50.3 per cent. non-black (16.9 white, 9.3 orange and 24.1 yellow); the series reared in laboratory light averaged 86.1 black and 13.9 non-black (4.7 white, 2.4 orange and 6.8 yellow); and the series examined from the outdoor pool averaged 86.6 black and 13.4 non-black (4.5 white, 3.1 orange and 5.8 yellow). Hence the salamanders reared in darkness contained about four times as much non-black in the body color as those reared in daylight in the laboratory or in the outdoor pool where the eggs were laid. The darkest individual in the series reared in darkness, with 70.5 black, was much lighter than the lightest, with 82 black, of either of the series reared in the light.

A Comparison of the Light Reactions of a Subterranean and an Epigeal Race of an Amphipod Species: A. M. BANTA, Station for Experimental Evolution.

The Spawning Habits of the Sea Lamprey, Petromyzon marinus: L. HUSSAKOFF, American Museum of Natural History.

The observations were made on the Nissequogue River at Smithtown, Long Island, June 1 and 2,

1911, while collecting material for an exhibition group of *Petromyzon* for the American Museum. The nests are depressions in the gravel of the river-bottom, two to three feet in diameter, and six inches deep at the center. The method of their construction and the general behavior of the specimens on the nest are very similar to those of the Brook Lamprey. But owing to the large size of this species all its movements can be minutely observed.

To be published in full in *The American Naturalist*.

On the Factors that Determine the Location of the Borings of the Yellow-bellied Sapsucker on the Paper Birch: MARGARET W. TAGGART, University of Illinois. (Introduced by Jacob Reighard.)

The aim of the present study is to determine the details of the work of the yellow-bellied sapsucker (*Sphyrapicus varius varius*) upon the paper birch (*Betula alba paprifera*). The borings of the sapsucker on the birch are distributed in several separate areas on a single tree. These individual holes are arranged in definite rows: they are distinct, small, numerous and are rarely confluent. The birds as they excavate eat the sap and cambium of the tree and also the insects attracted by the liberated sap. The factors involved in an explanation of the distribution of the groups of holes and in the shape and arrangement of the individual borings are two—the woodpecker instinct to bore holes and the mechanical conditions under which the bird works. The mechanical conditions resolve themselves into: (1) The perching of the bird. The sapsucker perches on knots and rough places on the bark, rather than on the smooth bark, and uses the excavations it has made in preference to the knots, because they afford a firmer foothold. (2) The structure of the bark. The shape of individual holes and the arrangement of series of holes in vertical columns is determined by the structure of the bark. (3) The use of the cambium as an article of diet. A flow of sap is released by the use of the cambium as an article of diet. The sap attracts insects as a purely incidental result of the bird's work. (4) The cleaning up of all the cambium around the edges of the holes. The large denuded areas are formed as an accidental accompaniment to cleaning up all the cambium around the edges of the holes, and may or may not appear on a given tree. Any explanation, therefore, which involves instinct or intelligence, more

than the general woodpecker instinct to make small holes, is unnecessary. The external factors are an adequate explanation of the facts in the case.

Control by the Sympathetic Nervous System and its Morphological Basis: ALBERT KUNTZ, University of Iowa.

To be published in the *Journal of Comparative Neurology*.

Nervous and Non-nervous Responses of Actinians: G. H. PARKER, Harvard University.

A few seconds after a mechanical or a chemical stimulus has been applied to the ectoderm of the lower part of the column of a sea-anemone (*Metridium marginatum*), the animal will respond by contracting the longitudinal entodermic muscles of the mesenteries, whereby the oral disk becomes retracted and ultimately covered by the action of the ring-muscle. The fibrillar layer in the base of the ectoderm and entoderm, believed by the Hertwigs to be the nervous layer, does not offer an easy means of explaining this reaction, since it does not connect the ectoderm in any direct way with the longitudinal mesenteric muscles. Neither does this layer become stained or impregnated by any of the ordinary methods used for the demonstration of nerve-cells or neurofibrils. By a modified silver method devised by Dr. E. G. Titus, a rich system of neurofibrils can be demonstrated in the supporting lamella of the column. These fibrils penetrate the ectoderm and reach through the supporting lamella of the mesenteries to the longitudinal mesenteric muscles. They are the essential nervous elements in the retraction reflex just mentioned.

When a sea-anemone is cut nearly in two, nervous transmission from one piece to the other can be accomplished through almost any part of the body of the animal except the lips. Yet in the lips the so-called nervous layer of the Hertwigs is as well developed as in any other part of the body. This layer, therefore, probably is not the true nervous system; the true nervous system consists of the nervous elements imbedded in the supporting lamella. The layer described by the Hertwigs as nervous is composed of the fine basal branches of the epithelial cells and may be a mechanism for

the absorption of nourishment from the fluids of the intervening spaces.

If a mechanical stimulus is applied to the middle of the column of a *Metridium*, in somewhat less than a minute a well-marked constriction encircles the animal, due to the contraction of the circular muscles of the column. This constriction will occur on a column whose ectodermic surface has been anesthetized with magnesium sulphate to such an extent that the characteristic retraction reflex can not be called forth from it. It is therefore probably a non-nervous direct response of the muscle comparable to the direct responses already demonstrated in the muscles of some sponges.

Preliminary Chemical Studies on Male and Female Producing Eggs of Pigeons: A Study of the Eggs of Forms in which the Dominance of Male and Female Sex and of White and Dark Color was Experimentally Determined by Professor C. O. Whitman: OSCAR RIDDLE, University of Chicago.

Much more important than the results of these preliminary chemical studies are the hitherto unannounced facts upon which the studies are based. One of the remarkable results achieved by Professor Whitman in his work with pigeons is the experimental control of the sex and color of the offspring of certain crosses of pigeons. That is to say, one and the same pair of birds can now be made to produce only dark male offspring—in spring and early summer, and when birds are young and in full reproductive vigor; and likewise only white female offspring—in late summer and autumn, and when birds are very old. The method consists simply in the choice of birds of known age and vigor for the matings, and then removing their eggs as fast as laid to other birds—thus forcing the birds throughout the year to their maximum of egg-production. All of the first several pairs of eggs produce dark male hybrids; while all of the last several pairs produce white female hybrids. A short transition period intervenes in which the sex and color of the progeny can not be foretold. There is usually a final period in which eggs are produced capable of little, and of no development. Birds thus treated over a period of years show that fewer and fewer

males are produced each succeeding year, and that the time of appearance of female-producing eggs is moved more and more toward the beginning of the season. Finally, matings of very old birds can be made in which it can be definitely foretold that only white female offspring will be produced. These results have been verified yearly since 1903. It is necessary of course to mate individuals of two different species, varieties or hybrids (one bird dark the other light if color is to be controlled) for such control. Four pure species (reciprocal crosses) and four different kinds of hybrids were successfully used in this way. Stated in Mendelian terms—terms which Professor Whitman did not think it well to use—he was able to shift, control or determine experimentally the dominance of sex and color. Aside from the fact that this discovery by Professor Whitman furnishes a starting point and a background for my chemical studies, it unfortunately seems necessary to emphasize at this time, that, although Professor Whitman had never announced this result, he had obtained it as early as 1903; and that this result—confidentially communicated—has been well known to his colleagues at the University of Chicago practically since that time.

The result of a limited number of parallel incubations and analyses made in 1911 on the male-producing and female-producing eggs obtained from the above-mentioned crosses indicate (number too small for final decision): (1) That eggs of smaller size, higher water content and smaller energy content (i. e., fewer units of physiologically available energy) can be correlated with maleness and dark color in the offspring. (2) That eggs of larger size, lower water content and greater energy content can be correlated with femaleness and white color in the offspring.

On a Relation Found to Exist between Changes in the Chemical Composition of a Membrane and Changes in its Permeability: OSCAR RIDDLE and ADELAIDE A. SPOHN, University of Chicago.

The follicular membrane can be taken for analysis at three different phases of its normal permeability to the constituents of yolk, viz: (1) When these constituents are penetrating the membrane very slowly; (2) when a sudden and very great increase in this rate of penetration occurs; and (3) the period following this increase and during which the greatly increased permeability is also accompanied by a rapid proliferation of the component cells of the membrane. Analyses show that in phase (1) when the permeability and

growth of this membrane are moderate in amount, the lecithin content of the membrane is of medium value (9 per cent.). At phase (2) the lecithin content is high (15-23 per cent.). During phase (3) the lecithin content again assumes a medium value (8.5 per cent.). The fat content is much lowest at phase (2) (=traces). In phases (1) and (3) this figure is 6 per cent. and 7 per cent., respectively. It has been shown that these values are not produced by variable amounts of contaminating yolk. The results seem to lend some support to Overton's theory of the lipid nature of the cell membrane; and indeed to indicate that that theory may be extended so as to apply to a *membrane of cells*. At any rate, here is one case where changes in degree of permeability of a *cellular membrane to substances rich in fat (yolk)* are preceded or accompanied by a change in the lecithin content of the component *cells* of the membrane.

Some Chemical and Hybridization Experiments in Invertebrates: MAX MORSE, Trinity College.

A number of crosses were attempted at the Harpswell Laboratory, South Harpswell, Maine, between the nemertean, *Cerebratulus*, and various invertebrates, such as *Echinarachnius*, *Ilyanassa*, *Strongylocentrotus* and others, both by simple mixing of eggs and sperms and by the application of hypertonic solutions and other reagents known by previous experiments to cause polar bodies to form or even to induce the earlier morula divisions of the egg. Of the several crosses attempted, only one was in any degree successful, this being *Cerebratulus* egg by *Ilyanassa* sperm, the polar bodies being extruded and the earlier segmentations passed through. However, even here it was found impossible to prolong the growth of the embryo to gastrulation, although temperature, salinity, alkalinity and other factors were considered. The cross in question was checked against errors in manipulation, contamination, etc. No experiment made according to the methods of Godlewski, Kupelwieser, *et al.*, where excessive amounts of sperm were used, were successful, nor were experiments involving normal fertilization, preceded by or followed by hypertonic or other parthenogenetic reagents, successful in causing even polar bodies to form. Hence *Cerebratulus* is similar to several other forms where attempted hybridization was found to be futile.

A Comparison of the Retardation Produced by Rapid and Slow Electrons (Beta Radiations) of Radium in the Growth of Various Seedlings and a Consideration of the Relative Importance of

Chemical and Physical Factors in the Process: E. D. CONGDON, Cornell University Medical College.

The method of comparing the effect of the rapid and the slow electrons consisted in the exposure of one lot of dry seeds (*Synapis nigra*, *Panicum germanicum*, *Amaranthus monstrosus*, *Nicotiana tobacum* and *Papaver somniferum*) to rapid electrons and another lot to a like intensity of rapid electrons plus secondary slow electrons coming from a lead tube. Both sets showed a retardation which decreased in amount with shortened exposure. The slow electrons had one fourth as great ionizing power in the air as the rapid electrons. Their retarding effect, however, was much greater than one fourth that of the rapid. In one case it was twice as great. Therefore, when very small seeds are taken so that the non-penetrating electrons can distribute their effect through the whole seed, the slow electrons, relative to their ionizing power in the air, are much more biologically effective than the rapid. It was also found that absence of seed coat increased greatly the effect, not only of the slow (non-penetrating) but of the rapid (penetrating) electrons. The placing of the embryo side of the seed toward the radium had a like effect. Those seeds with the greatest diameter were least retarded, and *vice versa*. Thus even in such small organisms, the largest having a diameter of only 0.67 mm., factors governing absorption play a great rôle in determining their sensitiveness. To determine the importance of chemical make up, pairs of seeds of like diameters but very unlike constitution as to starch and fat were exposed. The testa had been removed and the embryos all turned toward the radium. The pairs of species having seeds of like diameters showed almost identical degrees of retardation. The differing sensitiveness of the species here used must then be referred to physical rather than chemical differences in the seeds.

Studies in Developmental Energetics. I. The Changes in Chemical Energy during the Development of Fundulus heteroclitus: OTTO GLASER, University of Michigan.

Studies on the Artificial Production of Grafted and Multiple Embryos: A. J. GOLDFARB, College of the City of New York.

By a modification of the Herbst method of treating sea-urchin eggs, it was possible to produce either (1) fertilized eggs without their membranes, and with the blastomeres completely separated, (2) the same but with the blastomeres only partially

separated, (3) the loose union of one or more eggs or parts thereof, (4) the greater or less fusion of one and one half to sixteen or more eggs into one large complex.

Observations upon living and preserved materials clearly showed the nature of the subsequent history depended upon the nature of the union of the component eggs. When eggs or parts of eggs were either partially separated or brought in loose contact, the development of the component eggs was independent, showing no influence of the one upon the others. Two or more normal plutei resulted, either separate or welded together into twins. A very considerable number showed varying stages in the fusion and regulation whereby several blastulae or gastrulae were reorganized into one giant or irregular single blastula, gastrula or pluteus. These changes involved interesting regulatory processes in the skeleton, gut, size, shape, etc., of the individual eggs. They also showed an independent rate of development with a frequent dominance of one and the gradual reduction and disorganization of the other eggs in such a partially fused mass of eggs.

Common Atypical Embryos and the Diverse Methods by which they are Produced: A. J. GOLDFARB, College of the City of New York.

The Influence of Magnesium Chloride on the Fertilizing Potential of Spermatozoa: R. A. BUDINGTON, Oberlin College.

The sperm of *Arbacia punctulata* was used. This was treated for various lengths of time (5 to 80 minutes) with different solutions of MgCl in sea water; .1, .2, .3, .4, .5 and .6 gm. solutions were employed. Such sperm was then used in artificially fertilizing eggs of the same species, two questions being kept in mind, viz., (a) Will such sperm cause earlier cleavage of eggs than will normal sperm? (b) Will such sperm fertilize a larger percentage of eggs than will normal sperm? A positive result was obtained for the first problem when sperm were exposed to weak solutions for 5 to 15 minutes. As to the second problem, no marked increase in relative number of eggs fertilized, over the proportions shown by the control, could be detected.

The complete paper will probably be published in *The Biological Bulletin*.

The Effect of Narcotics upon the Development of the Hen's Egg: A. M. REESE, West Virginia University.

To be published in SCIENCE.

Effect of Commensal Plant Cells in Altering the Rate of Starvation in Scyphomedusae: ALFRED G. MAXER, Carnegie Institution of Washington.

The scyphomedusa *Cassiopea zamachana*, of Tortugas, Florida, is infested with Zooxanthellae, which when exposed to daylight operate through photo-synthesis to fix the carbon given off as a result of the medusa's metabolism, and at the same time to set oxygen free, thus serving as an efficient aid to the vital processes of the medusa. If the medusae be maintained in darkness, the zooxanthellae are rendered inactive, and the medusa starves more rapidly than if exposed to the diffuse light of the laboratory. In darkness the course of starvation is represented by the formula

$$y = W(1 - a)^x,$$

where y is the weight upon any day x after starving has begun, and W is the original weight when starving began. a is the index of starvation, for it increases as the rate of starvation increases. When the medusae are starved in darkness, a ranges from .075 to .205, but in diffuse daylight it is less, varying from .046 to .15. When the medusae are starved in diffuse daylight they lose weight more slowly than if in the dark, and the formula for starving in the light may be represented by

$$y = W(1 - a)x + \Delta \left(\frac{w + w(1 + \beta - \theta)}{2} \right) \\ \times [(1 - a)^{x-1} + (1 - a)^{x-2}(1 + \beta - \theta) \\ + (1 - a)^{x-3}(1 + \beta - \theta)^2 \\ + \text{etc.} \dots (1 - a)^{x-x}(1 + \beta - \theta)^{x-1} \\ + w(1 + \beta - \theta)^x],$$

where w is the original weight of plant cells in the medusa, β their coefficient of increase, θ their coefficient of mortality, and Δ the coefficient of assimilation of these cells by the medusa. The medusae may be starved 41 days, and still remain alive when their weight has been reduced to one hundredth of its original mass. If starved in seawater which has been sterilized by heating to 72° C., and then cooled to normal temperatures, the medusae lose weight about $1\frac{1}{2}$ times more rap-

	Movements Cease at	Temperature of Greatest Activity	Movements Cease at	Death Occurs at
<i>Aurellia</i> from Tortugas	7°.75 to 11°.8 C.	About 28° C.	36°.4 to 38°.4	38°.5
<i>Aurellia</i> from Halifax, Nova Scotia.....	—1°.4	18° to 23°	29° to 29°.7	29° to 30°

idly than if starved in sea-water which has been passed through filter paper but not heated. This leads one to suspect that Pütter's "dissolved food" in sea-water may not be available unless some bacteria or other organisms be present in the sea-water to stimulate or maintain a synthesis of the inorganic ingredients of sea-water that may result in building up the animal body. In other words, sea-water as such may not be a nutrient fluid for animals unless acted upon by certain plant-like organisms in the immediate presence of the animal itself. As a side issue of this research, it appears that the so-called "converse relation between ciliary and muscular movements" in ctenophores, trochophores, veliger larvæ, etc., is not a chemical but merely a mechanical matter. When the muscles contract pressure is brought to bear upon the ciliated cells, and this renders them relatively insensitive to stimuli and the cilia stop; *vice versa* when the muscles relax, as under the influence of magnesium, the normal stretching of the cilia-bearing epithelium is reduced and the cilia are free to beat incessantly, as do isolated cilia-bearing cells when mechanically torn away from the epithelium and set free in the water.

This paper may appear in the forthcoming volumes of "Researches from the Tortugas Laboratory of the Carnegie Institution of Washington."

The Temperature Reactions of Medusæ Ranging from Temperate to Tropical Oceans: ALFRED G. MAYER, the Carnegie Institution of Washington.

In species of *Aurellia*, *Limulus* and *Pennaria* which range from cold to warm seas, it is found that individuals living in the tropics have a higher optimum and a higher death temperature than have those living in cold seas. Also the individuals in the tropics can not withstand such low temperatures as do individuals of the same species in cold seas. For example, consider the case of *Aurellia aurita*, the common scyphomedusa, which ranges from pole to pole and is found in all oceans: *Aurellia aurita* from Tortugas, Florida, is killed if frozen into the ice, but specimens from Halifax, Nova Scotia, survive this treatment.

A strictly tropical medusa, such as *Cassiopea frondosa* is killed at from 8°2 to 9°7 C., but it continues to pulsate up to about 38°3-40° C. Evidently it could not survive in cold seas, and this may account for the fact that not a single species of *Cassiopea* has ever been found in the temperate regions. On the other hand, a form confined to arctic or cold seas, such as *Cyanea*

arctica from Halifax, Nova Scotia, pulsates until frozen into the ice, a treatment which causes it no apparent injury. On the other hand it is killed by 30° C. Thus it could not survive in the surface waters of the tropics and no *Cyanea* has yet been found in tropical waters. On the other hand the case of *Limulus* shows us that temperature resistance is by no means a sole factor in determining the geographical range of animals, for on the Massachusetts coast *Limulus* remains active from -1°1 to 41° C. and at the Marquesas Keys in Florida from 0.8° to 45°7 C. Yet it ranges only from Maine to Yucatan, and all attempts to introduce it upon the coast of Europe have failed.

This paper may appear in the forthcoming volume 5 of "Researches from the Tortugas Laboratory of the Carnegie Institution of Washington."

Symmetry in Regeneration: HERBERT W. RAND, Harvard University.

When a bilaterally symmetrical metazoan is bisected in a plane oblique to its long axis, regeneration, if it occurs, takes place in such manner that asymmetry, in the ordinary geometrical sense of that word, persists until regeneration is nearly or quite completed. The literature dealing with such experiments contains many descriptions which indicate or suggest that the new part, in the earlier stages of its regeneration, lacks, as regards form and organization, coordination with the old part; and that coordination of new and old parts to constitute a normal whole is secondarily effected by means of organogenetic and regulatory processes.

These descriptions give rise to misconceptions regarding the true nature of the regenerative process. A reinvestigation of regeneration from oblique surfaces in planarians reveals evidence that the new material is, from the very beginning of the regenerative process, in the highest degree coordinated with the old. While, during regeneration, the total material is asymmetrical in a geometrical sense, nevertheless a perfect organic symmetry exists in the sense that such materials and energies as are present are distributed upon either side of a morphological median surface (not a plane surface) with precise regard to a certain completeness of plan which remains to be worked out only in a quantitative way. This unity of organization certainly exists from the moment when the formation of new tissue begins—perhaps even before regeneration is outwardly manifested.

The Larva of Sarcophaga, a Parasite of Cistudo Carolina, and the Histology of its Respiratory Apparatus: WM. A. KEPNER, University of Virginia.

This *Sarcophaga* has only been observed three times. Packard discovered it first. He took it to be an *Cestrus* larva. Wheeler later succeeded in raising imagines from the larvæ and found that the flies belonged to the genus *Sarcophaga*. A careful study of the larvæ taken from a *Cistudo Carolina* in Virginia also revealed that these were larvæ of a *Sarcophaga* and not those of an *Cestrus*. The anterior stigmata are laterally compressed fan-shaped processes. Each stigma represents for the most part a proliferated mass of the two-layered cuticle of the general surface. At its wide free end the anterior stigma bears 16 to 18 finger-like papillæ. At the tip of each papilla there is a pore which opens into a branch of the lumen of the stigma. The lumen of this anterior stigma is filled with a finely reticulated plug of chitin. Just as the tracheidia of the main trachea are given off by the inner, denser cuticular lining of the trachea so the reticulated plug is given off by the inner, denser layer of the cuticular substance of the anterior stigma. The larvæ spend three or four days in emerging from the skin of the host. It is inferred that during this time the anterior stigma are functional, and that the reticulated plugs act as bacterial screens for the two main tracheal trunks.

The complete paper will be published in the *Biological Bulletin*.

The Intra-uterine Embryo of the Bonnet-head Shark, Sphyrna tiburo: E. W. GUDGER, State Normal College, Greensboro, N. C.

This shark is viviparous, but viviparity is not attained by a villous uterus secreting a "milk" as in *Dasyatis say* and *Pteroplatea maclura*, two rays common on our Atlantic coast. The inner mucous lining of the uterus is separated from the outer muscular coat by a fibrous spongy material, hence considerable growth of the embryos may take place before any distension of the outer wall is necessary. The embryos in the fish captured measure 50 mm. in length. They lie nested in the cavity of the uterus, each in a separate spindle-shaped compartment or depression in the mucous lining. The embryos have a large number of external gill-filaments 15-18 mm. long protruding from the gill-slits. The umbilical cord is about 50 mm. long and is closely beset with what Alcock

has called "appendicula," large clear villi-like structures, sometimes single, sometimes formed. The yolk-sac is large and flat. Each egg with its embryo is contained within a very thin but tough and elastic membrane, highly iridescent in appearance. The ends of this shell are curiously plaited and folded and when unfolded the shell becomes of great length. The purpose of this seems to be to accommodate the growing embryo, since Alcock found the 18-inch young of *Zygæna blochii*, the Indian Hammer-head, still enclosed in the shell. The same authority reports that the emptied yolk-sac becomes adherent to the wall of the uterus and thus becomes a functional placenta. The embryos under consideration are too young to show anything of this kind. The function of the "appendicula" is not known. The data given are from a shark studied at the Beaufort, North Carolina, Laboratory of the United States Bureau of Fisheries.

This abstract represents a part of a paper on "Viviparity in Beaufort, N. C., Sharks and Rays," which will probably be published in the *Bulletin of the U. S. Bureau of Fisheries*.

Amitosis in Testes of Tenia serrata: R. T. YOUNG, University of North Dakota.

Occasional evidence of amitosis is found in early stages of these organs, consisting in (1) cells which show distinct incisions of the cytoplasm, (2) cells with straight or nearly straight edges separated by narrow spaces, as though recently broken apart, and (3) bi-nucleate cells constricted between the nuclei.

Epithelium of Plathelminths: R. T. YOUNG, University of North Dakota.

To be published in the *Journal of Morphology*.
Some Uses of Celluloid in the Biological Laboratory: J. S. KINGSLEY, Tufts College.

Small skeletons like those of the frog and *Necturus*, bleached tests of sea-urchins, etc., are sure to be quickly destroyed by students unless protected in some way. For some years I have used boxes of glass, fastened together with paper or tape, for this purpose, but recently, acting on a hint from Dr. Gast, of the Naples Zoological Station, I have made the boxes of transparent sheet celluloid, sometimes with one side of glass. The celluloid is such as is employed for automobile wind-shields and comes in sheets measuring 20 by 36 inches. The thickness is accurately gauged and is in multiples of 5/1000 of an inch. I have mostly employed 10/1000 and 15/1000, the cost of the former being 75 cents, the latter \$1.00 a sheet.

The celluloid is cut with the shears to the required size and shape and the boxes are built by cementing the edges of the sheets by bringing them into the desired position and then moistening them with acetone applied with a small brush. Less than a minute is required for the firm adhesion of the edges. In the same way the celluloid can be fastened to the edges of a light of glass, provided that the edges of the latter be clean. Of course considerable care must be exercised to see that all pieces of celluloid be accurate in size. The details of the operations are not easily described, but a little experience will enable any one to devise methods to meet all cases. The specimen can be fastened to the glass or celluloid by means of scraps of the waste celluloid dissolved in acetone. I have now fluid specimens mounted in "Wilson's oil" and enclosed in boxes of celluloid, built up in the same manner, which have been in good condition for several months. How permanent they will prove, time can only decide. It is impossible to mount them in alcohol or formol as water or alcohol dissolve the camphor and other substances in the celluloid. In the case of Wilson's oil the box must be completely filled or there will be a warping of the celluloid which will break down the box in a few days. I believe that celluloid can be used to fasten the tops to the square museum jars, but I have not tried it. I may suggest that strips of celluloid be fastened to the ground edge of the jar by acetone, the jar be then filled as completely as possible with the preserving fluid without wetting the edge of the celluloid, and then the cover applied, acetone being run in with a brush, and then a solution of celluloid in acetone being painted over the joint. It seems probable that, with such a thin layer of celluloid, there would not be sufficient warping to break the joint. It is often desirable to mount rather thick microscopic objects under pressure. I have used the following process in thus mounting parapodia of annelids. Two narrow strips of sheet celluloid are placed on a slide in the desired position and are then cemented to the slide by running acetone under them. The object, properly cleared, is placed between the strips, and the cover-glass pressed down and fastened in position with acetone run under. In two or three minutes balsam or dammar is drawn under the cover by capillary attraction and the slide is permanently mounted. I may say that the sheet celluloid is to be had in every large city. I have bought my supplies of Willard and Willard, 65 Bedford Street, Boston. The scraps from other

operations may be used, instead of gun-cotton or celloidin, for section cutting, being dissolved in alcohol and ether in the customary manner.

Parasites of the Muskrat: F. D. BARKER, University of Nebraska.

On the Number of Known Species of Animals: H. S. PRATT, Haverford College.

The first enumeration of all the species of animals known to science was made by Linnaeus in 1758. In the tenth edition of the "*Systema Naturæ*" he described 4,236 species, which were apportioned among the various larger groups (which are here given their modern names) as follows:

Mammals	183
Birds	444
Birds and Amphibians	181
Fishes	414
Tunicates	3
Bryozoa	35
Mollusks and Brachiopods	674
Crustaceans	89
Arachnids	78
Myriapods	16
Insects	1,936
Worms	41
Echinoderms	29
Cœlenterata	74
Sponges	11
Protozoa	28

About a hundred years later (1859) Agassiz and Bronn made the following enumeration:

Vertebrata	18,660
Mollusks	11,600
Crustaceans	1,500
Arachnids	2,000
Insects	90,000
Worms	1,600
Echinoderms	550
Cœlenterates	1,820
Sponges	290
Protozoa	1,510
	129,530

In Ludwig's revision of "*Leunis*," published in 1886, the numbers of species are given as follows:

Mammals	2,300
Birds	10,000
Reptiles	2,500
Amphibians	1,000
Fishes	9,000
Tunicates	300
Mollusks	21,320

Crustaceans	5,600
Arachnids	4,000
Myriapods	800
Insects	200,000
Worms	6,300
Echinoderms	2,370
Cœlenterates	3,000
Sponges	600
Protozoa	4,130

273,220

An estimate of the number of living species known at the present time (1911) gives the following results:

Mammals	3,500
Birds	13,000
Reptiles	3,500
Amphibians	1,400
Fishes	13,000
Tunicates	1,300
Mollusks	61,000
Crustaceans	16,000
Arachnids	16,000
Myriapods	2,000
Insects	360,000
Annelids	4,000
Bryozoa	1,700
Rotifers	500
Nemathelminthes	1,500
Plathelminthes	5,000
Echinoderms	4,000
Cœlenterates	4,500
Sponges	2,500
Protozoa	8,000

522,400

Some Changes in the Nerve Cells of the Bee during its Life Cycle: W. M. SMALLWOOD, C. G. ROGERS and RUTH L. PHILLIPS, Syracuse University.

Ecological Observations in British Guiana and Brazil: HENRY E. CRAMPTON, Columbia University. (Illustrated with lantern slides.)

An Early Human Cranium from Unterlesece near Trieste: HARRIS HAWTHORNE WILDER, Smith College.

A fragmentary human cranium was exhibited which was excavated during the past summer in a cave in the small Slavic village of Unterlesece, 15 kilometers east of Trieste, Austria. The cavern is a mere cleft, not offering sufficient headroom to allow one to stand, or even sit, except at the very end, and could not have served for a dwelling. The deposits, therefore, consist of the things that have washed in and lodged in the hollows of the floor. They consist mainly of the bones of Neo-

lithic animals, and a few Neolithic shards. This fragment was found, associated with a right ulna, and a small shard of crude workmanship, in a bottom layer of clay, and covered by a distinct layer of loess, with stone fragments from the roof, among which were imbedded bones of the ox, sheep, horse, etc., also many pieces of a human skeleton with worn teeth, as in the American aborigines. The results of the detailed anthropometric measurements, of which 37 were taken, conform closely to certain other ancient skulls of the *sapiens* species, especially those of Egisheim, Cannstatt, Brunn, I. (1885), and probably Tilbury and Sligo. While, however, these latter are pretty definitely Quaternary (Solutrean, Magdalenian), this specimen, as dated by the shard and the general character of the remains in the cavern, must be either Neolithic or Transneolithic (Campignyan, Tardenoisian).

Evidence of Evolution in the Mechanism of Inheritance: MAYNARD M. METCALF, Oberlin College.

In some, perhaps in all, of the higher animals and plants the chromatin consists of discrete particles of different functions in physiologic activity and inheritance. These particles are grouped into chromosomes in which, in some species—perhaps in all—they form linear aggregates. There is an elaborate achromatic mechanism of mitosis which aids in securing the distribution of halves (?) of each discrete particle of chromatin to each of the two daughter nuclei. In many plasmodrome protozoa (perhaps in some stage of their life history in all of them) the nucleus contains a caryosome with a definite caryole and an outer membrane delimiting it from the peripheral zone of the nucleus. New granules of chromatin continually form in the caryosome (apparently at the caryole), wander to the caryosome membrane, after a time break through this into the peripheral zone of the nucleus, through which they migrate to reach the caryotheca. Many of these granules in time break through the caryotheca into the cytoplasm as chromidia, there to be dissolved. Apparently any of the granules so formed in the nucleus may become chromidia. The most careful study of these nuclei shows no indication of division of the chromatin granules within the nucleus during this formation of chromidia. Whole granules seem to be thrown off. Such a condition seems incompatible with the existence of a series of "determiners" in the nuclei of plasmodroma. The chromatin seems rather more homogeneous, each particle having the

same physiologic and inheritance value as every other except perhaps for size or density. This condition parallels the general physiological condition in the plasmodium whose protoplasm shows little differentiation for sensation, conduction, locomotion or specialized secretory activities, each bit of the protoplasm sharing in all these activities. In other protozoa we find several different types of more highly evolved chromatin structure. Some of these, as in *Opalina*, seem not in the line of evolution of the metazoan condition. Others, as in *Paramecium*, have chromosomes which are linear aggregates of granules and which split longitudinally in mitosis. Such a form has a chromatin arrangement which would allow differentiation of the granules into divergent determiners, for a portion of each granule is given in mitosis to each daughter nucleus.

A further discussion of this subject is in preparation. Its place of publication is not yet determined.

Opalina mitotica: MAYNARD M. METCALF, Oberlin College.

This paper, which was read by title only, will soon appear in full in one of the Spengel Festschrift volumes of the *Zoologischer Jahrbücher*.

The Pædogamous Conjugation of Blepharisma: GARY N. CALKINS, Columbia University.

There is some question as to the specific name of the organism with which I am working. Up to the present I have followed Butschli in calling it *B. musculus*, identifying it with the form *Urostyla musculus* described by Ehrenberg. The name *Blepharisma* goes back only to Perty in 1849, who first used it as a generic name for a species of *Spirostomum* described by Ehrenberg again, as *Spirostomum lateritia*. Leaving for the present the taxonomic position of the organism I wish to speak here more particularly of some of the biological phenomena which have come under observation during the five months that I have kept *Blepharisma* under culture. I isolated a specimen in July from pond water at Woods Hole and found that it lends itself readily to cultivation upon artificial media. For the best results a few drops of pond water plus a drop of 24-hour standard hay infusion are now used, a medium upon which the organisms have reached to-day the 160th generation. None of the earlier observers made out a micronucleus and from total preparations alone I was unable to demonstrate it. Upon study of sections of the organisms, however, I have been able to find structures which undoubtedly correspond

with a micronucleus in the typical ciliate. The macronucleus is large and comparatively easy to demonstrate, although it has a variety of forms; sometimes it is a single body of spheroidal form, again it breaks up into irregular fragments. On division there are two chief portions, one at either end, and a connecting strand of somewhat different texture and the micronuclei are connected with this. It is the custom of all who carry on careful culture work to isolate one individual and supply it with fresh medium every day. The individuals left over after isolation of the one specimen are placed in larger vessels and kept as "stock." Early in the summer it was seen that endogamous conjugations occurred frequently in this stock material, in some cases reaching the proportions of a general epidemic. So keen at times is this "sexual hunger" as Maupas called it, that conjugation occurs between the closest related cells. For example an individual was isolated in the 104th generation, fresh medium and food being given as usual. On the following day it had divided, but the two sister cells were united in typical conjugation. This, I believe, is the closest relation on record for pædogamous conjugants amongst Infusoria. The cells begin to conjugate at the anterior tips as in *Paramecium* and gradual fusion extends along the peristome for about two thirds of the length and never further, thus leaving the greater portion of the undulating membrane and the mouth entirely free. They remain in conjugation from 12 to 24 hours and separate through vacuolization of the connecting zone of protoplasm. The most remarkable phenomena are connected with the nuclear relations during conjugation on which I can now give only fragmentary notes, as my observations are not completed. The macronucleus becomes compact and spheroidal with a typical "kernspalt" in the center. It is also enclosed in a firm resistant membrane like a cyst, a structure which does not exist at other times. Sections of conjugating pairs show that the nucleus is made up at this time of two main bodies of chromatin of densely granular appearance, while between them long drawn-out rods of chromatin like chromosomes appear to be dividing. This central material gives rise to two smaller nuclei which are freed from the mass of macronuclear material and in the cytoplasm undergo one or two further divisions which result in the gametic nuclei. I have not yet found the pronuclei in the process of fusion, but have seen them in the connecting bridge between the

two organisms. Here then is something entirely novel in the make-up of macro- and micronuclei, the micronucleus being absorbed and protected by the macronucleus. The size statistics of conjugating and non-conjugating forms are similar in essence to those of *Paramecium*. Miss Watters has measured some 1,580 specimens, of which 482 were conjugating. The average size of the conjugants is 110 μ , of non-conjugants 140 μ , the latter including exconjugants which never regain normal size. More than 150 exconjugants have been isolated and maintained from time to time. Not one has lived more than 16 days, the dates being 22 per cent. dead on first day, 31 per cent. on second, 13 per cent. on third and 8 per cent. on fourth, with the rest scattering one or two per day until the sixteenth. This is similar to Bütschli's results with *Blepharisma* in 1876, when all of the ex-conjugants died within three days after separating. Vitality therefore is not restored by conjugation under the conditions of the experiments; whether it is due to these conditions, due to the pedogamic nature, or due to some other cause remains to be shown.

It is expected that this paper will be published in full in the *Journal of Morphology*.

Actinobolus radians St. and its Cultivation: GARY N. CALKINS, Columbia University.

Regeneration in Paramecium caudatum: FLORENCE PEEBLES, Bryn Mawr College.

The results of a series of experiments on *Paramecium caudatum* show that the power of regeneration varies greatly in different races, and also in individuals of the same race. It usually depends on the condition of the protoplasm, or the age of the individual at the time of the operation. The removal of the anterior one third causes greater disturbance in the cell than the removal of the posterior end. The fragment which is removed always dies, but the larger nucleated piece either regenerates the lost end or divides without regeneration into a normal and an abnormal individual. Regeneration of the anterior end took place in forty per cent. of the cells, while the posterior end regenerated in sixty-three per cent. Cells in the vegetative condition when cut in half form no abnormal individuals. One half dies and the other produces a normal race. It was found impossible by removal of the protoplasm to produce a small race from a large one. After several generations the normal size was restored. Vegetative cells seem to have much division energy stored up within them. Experiments indicate that three

division planes are present, so that one cell represents four individuals. The removal of a part of the protoplasm acts as a stimulus, and several divisions follow in quick succession. It was found impossible to cut the macronucleus in vegetative cells so that each fragment contained a part of it. When cells were cut in half during division both pieces received a fragment of the nucleus and formed normal races.

It is expected that this paper will be published in full in the *Biological Bulletin*.

Observations on Synapsis and Reduction: EDMUND B. WILSON, Columbia University.

The maturation-phenomena in *Tomopteris* and *Batrachoseps* have been reexamined by a study of the original preparations of the Schreiners and of Janssens, as well as of new preparations of *Batrachoseps* fixed and stained by various methods. This study has led to a confirmation of the main conclusions of the above-named observers in regard to synapsis. The seriation of the stages is placed beyond doubt by the conditions seen in *Batrachoseps*. In both this form and *Tomopteris* the facts seem to admit of no other interpretation than that the "amphitene" or synaptic stage represents a progressive union of leptotene threads, two by two and side by side (parasynapsis), to form pachytene loops of the haploid number; and in the case of *Batrachoseps* there is considerable evidence that this process is accompanied by a close torsion or twisting together of the leptotene threads as they unite. This process proceeds from one pole of the nucleus towards the opposite pole. In the opinion of the author it is impossible to admit the interpretation of this process offered by Fick, Goldschmidt, Haecker and Meves that it is only a modified form of longitudinal splitting. Observations on the Orthoptera (grasshoppers) indicate that a similar mode of synapsis occurs in these animals, though it is less certainly shown than in the other forms. In the pachytene loops resulting from synapsis all traces of duality are usually lost to view, at least for a time. This may be due either to a close twisting together of the leptotene threads or to an actual process of fusion. In either case there is as yet no satisfactory evidence that the plane of the ensuing "reduction-division" is identical with that of the original conjugation. The facts point on the whole to the conclusion that the period following synapsis is one of reorganization of the chromosomes in which a redistribution of their substance may take place. This may be effected by a process of torsion as the chromo-

somes unite, or subsequently, followed by a new longitudinal split in a new plane, as suggested by Janssens in his theory of the chiasmotype. The conception of the "reduction-division" is however valid, since this division reduces the valence of the bivalent to one half, and it fails to take place in the case of univalent chromosomes, as is proved by the history of the sex-chromosomes, *m*-chromosomes and supernumerary chromosomes in the Hemiptera. The explanation of the Mendelian disjunction may be sought in either maturation-division or in both, as has been shown by Janssens.

The Penetration of the Spermatozoon and the Origin of the Sperm Aster in the Egg of Nereis:

FRANK R. LILLIE, University of Chicago.

(1) As described in a previous paper,¹ the egg of *Nereis* secretes a large quantity of jelly, derived from spherules of a cortical layer, immediately after contact of the spermatozoon. The perforatorium of the spermatozoon penetrates the vitelline membrane and becomes inserted in a well-marked entrance cone. *Fixation granules*, undoubtedly derived from the spermatozoon, appear at the tip of the perforatorium in the cone. The substance of the cone becomes differentiated by staining reaction and behavior to form an organ definitely concerned in the subsequent penetration of the spermatozoon. (2) The spermatozoon remains external to the egg embedded in the jelly for 45 to 50 minutes after attachment. The head is then drawn by the cone through the vitelline membrane into the egg in the form of a thick strand of chromatin several times the length of the original head of the spermatozoon. *The middle piece and tail remain external*, and may be seen on the vitelline membrane up to the time of cleavage. They never enter. (3) The chromatic thread representing the head of the spermatozoon then contracts to form a vesicular nucleus, still attached by the perforatorium to the cone. Nucleus and cone then rotate through 180° and the sperm aster arises always at the point of the nucleus farthest from the cone, thus in the position of the base of the sperm head. The problem of the origin of the sperm centrosome in the egg is considered in the next abstract. (4) The "fixation granules" are possibly cytoplasmic elements introduced by the spermatozoon, though they come from the apex of the spermatozoon. No other demonstrable cytoplasmic elements are introduced by the spermatozoon. (5) After origin of the aster the sperm nucleus separates from the cone, and the latter

gradually disintegrates in the cytoplasm. The sperm amphiaster becomes the cleavage amphiaster.

On the Fertilizing Power of Portions of the Spermatozoon: FRANK R. LILLIE.

If unsegmented eggs of *Nereis* be centrifuged about 60 revolutions of the hematocrit of the Bausch and Lomb hand centrifuge in about 40 seconds, thirty to forty minutes after insemination, the mass of eggs accumulates at the distal end of the tubes and becomes pressed together. The jelly, which is of less specific gravity than the eggs, then separates from the latter and forms a layer above the eggs. In squeezing through the narrow interstices between the closely packed eggs it rubs over the surface of each egg, and in many cases it carries the attached spermatozoon away with it. In other cases, especially if the eggs are centrifuged shortly before the time of penetration of the spermatozoon, it draws out the substance of the head of the spermatozoon, which is very ductile at this time, into a strand; and in numerous cases it carries away the tail and middle piece, or variable portions of the head in addition. Partial sperm-heads of all sizes are therefore left attached to the egg by the perforatorium. Such partial sperm-heads then penetrate, being drawn in by the entrance cone as in the case of normal fertilization, and they form partial sperm-nuclei attached to the entrance cone within the egg. Rotation then takes place and an aster invariably arises in connection with the partial sperm-nucleus at the point most distant from the cone, *i. e.*, at the most basal point of the sperm-nucleus. By using large quantities of eggs and by preserving at various stages one can study all stages of these processes in sections, and the above statements are based upon large numbers of observations. It is therefore proved (1) that the sperm centrosome is inessential for formation of the sperm aster within the egg; (2) the origin of the sperm aster is a nucleocytoplasmic reaction; (3) the sperm-nucleus is polarized with reference to this reaction inasmuch as the sperm aster arises always at the most basal point of the partial sperm-nucleus, with reference to the orientation of the nucleus in the sperm head. The conclusion therefore involves the conception of a certain differentiation between egg-nucleus and sperm-nucleus, for the former has no independent capacity of initiating karyokinetic phenomena, whereas the latter has.

The two preceding papers will be published in full in the *Journal of Experimental Zoology*.

Human Spermatogenesis: T. H. MONTGOMERY, JR., University of Pennsylvania.

The point was made that in man there are four types of probable functional spermatozoa, differing in their content of modified chromosomes. One type has two of these bodies, one has none, one has the larger body only and the other has the smaller only. All primary spermatocytes contain each one larger and one smaller modified chromosome. Further, during the histogenesis of the sperm the cuff of the spermatid is produced from nuclear sap, not from the cytoplasm, and since this cuff substance is thrown away with the abstricted cytoplasm the spermatid loses the greater amount of its nuclear sap. Therefore, this nuclear sap substance can not have the same value in inheritance as the other substances of the nucleus.

The X-element in Guinea-chicken Hybrids: MICHAEL F. GUYER, University of Wisconsin.

The hybrids in question, all male, were the offspring of a black langshan cock and a common guinea hen. The X-element of the chicken is very large, of stout build and typically of different shape from that of the guinea. While each usually appears as a curved body, the X-element of the chicken is U- or bean-shaped with both ends of the same size, while that of the guinea is more comma- or pistol-shaped, with one end noticeably narrower than the other. The X-element of the hybrid was found to be invariably of the maternal (guinea) species type. In this fact may lie a simple explanation of why these hybrids were all male. For in all known cases it is the spermatozoon *without* the large X-element which unites with the egg in the production of the new male, and since such a spermatozoon is much smaller than one of the other type, this mere difference in size may be the factor determining which shall fertilize the egg. Hybrids are obtained with difficulty even under the most favorable conditions and we may reasonably suppose that the egg-plasm is more or less resistant or antagonistic to the entrance of a foreign sperm. If such is the case it would seem not improbable that the smaller type of spermatozoon with its diminished quantity of incompatible substance and its lessened surface against which resistance could operate, would penetrate more readily than the other, with the consequent production of a male.

To appear in full in *Journal of Morphology*.

Eight Factors that Show Sex-linked Inheritance in Drosophila: T. H. MORGAN, Columbia University.

Eight factors that show sex-linked inheritance have appeared in cultures of the fruit fly, *Drosophila*. These factors without exception follow in their heredity the distribution of the sex-chromosomes with which they may be said to be linked. (1) The red eye of the wild fly is due to three factors—vermillion *V*, pink *P* and orange *O*. Of these *V* is not sex-linked, while *P* and *O* follow the sex-chromosomes. The red eye may be designated by *VPO*, the pink eye by *vPO*, the vermillion eye by *VpO* and the orange eye by *vpO*. Orange is present in all these cases, but since like *P* it is sex-linked (see below), it occurs in duplex in all females and in simplex in all males. The heredity of these eye colors has recently been published.* (2) A new color has more recently appeared, due to the loss of the orange factor. The formula for this mutant seems to be *l'Po*. The females have darker eyes than the males; thus giving a dimorphic race. The *O* factor proves to be sex-linked. It will now be possible, unless associative inheritance interferes, to produce a new series of reds, vermilions and pinks that lack orange; and an eye that lacks all color determiners, but contains the color producer *C*. (3) White-eyed mutants due to the loss of the color producer *C* have been described,² and these may carry the determiners for vermillion, pink or orange, etc. (4) The gray color of the wings of the wild fly is due to three factors—black *B*, yellow *Y* and brown *Br*. The formula for the wild fly is *BYBr*; for the black fly *ByBr*; for the yellow fly *bYBr*, and for the brown fly *byBr*. Of these three factors black, *B*, is sex-limited; yellow, *Y*, is not; and *Br* has not yet dropped out, so that its distribution is unknown. (5 and 6) Two wing mutants, described as rudimentary wings and miniature wings, both show sex-linked inheritance.⁴ The miniature wing is due to the loss of a factor *S*; its formula is *Ms*. The rudimentary or "short" wing is *Sm*. When a miniature female is crossed with a short male, all the females (*Ms Sm*) have long wings; all the males (*Ms..*) have miniature wings. When the "short" female is crossed to the wild male all the females (*Sm SM*) have long wings, and the few males that appear have short wings. The females are to the

**Jour. Exp. Zool.*, 1911.

²SCIENCE, 1910.

⁴SCIENCE, 1911.

males as three hundred and eighty-one to three (381:3). (7) The bands on the abdomen, so conspicuous a feature of the normal fly, have been lost in another mutant. The factor is dominant and sex-linked.* (8) Another wing mutant has appeared in which the second inner vein fails to reach the margin, often producing a bifid wing, but the shape of the wing is varied. The wings are held out at right angles to the sides of the body. The factor responsible for this condition is also sex-linked. Thus bifid-winged females crossed with wild males give all normal-winged females and bifid-winged males. The reciprocal cross gives normal-winged males and females. These inbred give normal-winged females and males and bifid-winged males.

Supernumerary Chromosomes and Conjugation of Chromosomes in Ceuthophilus (Sp.): N. M. STEVENS, Bryn Mawr College.

The usual number of chromosomes in the spermatocytes of the first order is 19, eighteen bivalents and the univalent X chromosome. In one individual two supernumeraries, and in another one were found. These supernumerary chromosomes behave like those in *Diabrotica savor* and *D. 12-punctata*, dividing sometimes in the first, sometimes in the second maturation mitosis; and they probably originate, as in the *Diabroticas*, in an abnormal division of the X chromosome. In *Ceuthophilus* synapsis or conjugation of the chromosomes takes the form of parasynapsis. The chromatin threads pair side by side, twist together and in the prophase untwist. The homologous members of each pair unite end to end, forming compound rods, crosses or E-shaped figures, or they may unite by both ends, forming rings. The first maturation mitosis is a segregation division, the second equational. There is no synizesis stage, and no marked polarization of the chromosomes to form a bouquet stage.

This paper will be published in full in the *Biological Bulletin*.

Chromosome Studies: F. PAYNE, Indiana University.

A continued study of the Reduviidæ throws no further light upon the origin of the irregular chromosome distribution found in that family. In *Phorontis*, however, is found a type of distribution new to the family and similar to that of *Gelastocoris oculatus*. In *Pselitodes*, which gives another type similar to that of *Prionidius* and *Sinea*, the single chromosome, the homologue of the small

idiochromosome, contains a larger quantity of chromatin than the three small chromosomes which go to the opposite pole. In this respect it is similar to the case of *Acholla*. A study of the ovaries of *Gelastocoris* reveals a nucleolus which forms shortly after the last oogonial division and remains until about the time of synapsis. In most cases this nucleolus stains uniformly, but in favorable places darker bodies can be seen within it. It seems probable that these darker bodies are the idiochromosomes, eight in number. In these ovaries the ova can be traced with unbroken continuity from the end chamber to the fully developed eggs.

To be published in full either in the *Journal of Morphology* or in the *Biological Bulletin*.

The Histogenesis of the So-called Apyrene Spermatozoa in Strombus: EDWIN E. REINKE, Princeton University.

The apyrene spermatozoon of *Strombus*, as compared with the eupyrene or ordinary spermatozoon, of this species, is a very large cell with a complex structure. The cell-body is cylindrical and tapering in shape and it is filled with many polygonal bodies which are undoubtedly composed of albumen. These bodies are very regular in outline and are arranged in rows; they vary considerably in size, those in the middle of the cell being larger than those at either end. The breadth of the cell is greatly increased by the presence of two undulating membranes which pass down either side of the cell and meet at the posterior end, where they are drawn out into a long sharply pointed tail-piece. Anteriorly these membranes fuse in the mid-line and give a broad, rounded appearance to this end of the cell. At the very tip, where the membranes meet, there is a darkly-staining cap; this is a centrosomal structure. Lying scattered through the cell and between some of the albuminous bodies are fragments of greatly degenerated nuclear material. The entire length of the spermatozoon is about 90 micra. The apyrene spermatozoa are found to originate from certain large pear-shaped cells which are attached by their narrow ends to the cyst-wall of the testis. These cells are easily recognized and can readily be distinguished from the eupyrene spermatocytes, not only by their size, but also by the presence of a large sphere with strong astral rays. The development of the apyrene spermatozoa from these cells is direct, that is, no cell-division occurs during their histogenesis; the nucleus simply breaks down, scattering nuclear fragments throughout the cell. These fragments immediately begin to degen-

* *Proc. Soc. Exp. Biol. and Med.*, 1911.

erate and play no further active part in either the developing or the adult spermatozoon. At the time of the breaking down of the nucleus, the large sphere with its astral system disappears, leaving only the contained centrioles and a mitochondrial mass which surrounded it. There are a great many of these centrioles and, lying close together at the periphery of the cell, they very soon divide and one half of the resulting granules begin to move across the cell. In this way a large bundle of very thick axial fibers is formed and its subsequent growth greatly increases the length of the cell. Before it has reached its full growth, however, the bundle splits down its long axis. Continued growth causes each half of the bundle to pass to opposite sides of the cell. Here, by fusing and pushing out the cell wall, they eventually form the undulating membranes. The albuminous bodies first appear a short time before the bundle of axial fibers begins to split. They are formed by the filling up with albumen of previously existing vacuoles. At first these bodies are spherical, but later, through crowding, they become polygonal. The foregoing facts, relative to the development and the adult structure of these cells, would indicate that their function, if any exists, must be widely different from that of the ordinary spermatozoa. Indeed, the evidence at hand is almost strong enough to make the application here of the word spermatozoon, in its specialized meaning, a misnomer.

Reinvigoration Produced by Cross Fertilization in Hydatina senta: DAVID D. WHITNEY, Wesleyan University.

A report of experiments was given in which Dr. Whitney has reared rotifers for five hundred generations by the parthenogenetic method. The females of each generation laid eggs and these at once without fertilization by a male grew into females for the succeeding generation. Dr. Whitney observed two long experiments for about three years and found that these animals gradually became weaker and weaker by this maleless method of reproduction and finally died out from general weakness if the experiments were carried on long enough. One of the races lived for 385 generations and the other is still alive in the 503d generation, but is in a very weak condition. When both races were alive and had reached a weakened condition males were produced from them and some inbreeding experiments were made in which eggs were fertilized by the sperm of the males of the same race. This was done in order to deter-

mine whether fertilization would bring the race back to normal vigor. Several successive inbreeding experiments were made and only resulted in a slight amount of reinvigoration of either race. However, when the two weak races were cross-bred a great amount of reinvigoration occurred at once and the resulting race was as vigorous as any young normal race.

To be published in full in the *Journal of Experimental Zoology*.

External Agents and the Growth Period of the Egg in Hydatina senta: A. F. SHULL, University of Michigan.

It is not possible to reduce the proportion of male-producers in this species of rotifer by transferring to manure solution eggs that have been laid in spring water, even though the manure solution is strong enough to exclude male-producers when the rotifers are bred continuously in it. The nature of the females is determined, therefore, before they hatch. A female that has already produced some male-producers, ceases almost immediately to yield male-producers if she is placed in manure solution. A female that has produced part of her family (all female-producers) in manure solution, may commence to bring forth male-producers almost immediately if she is transferred to spring water. The kind of female which will hatch from an egg is determined, therefore, within a period of two or three hours before the egg is laid. This period includes the entire growth of the egg and the formation of the single polar spindle.

The complete paper will appear in the *Journal of Experimental Zoology*.

Notes on the Inheritance of Barring: H. D. GOODALE, Station for Experimental Evolution.

Some Reactions of Drosophila to Parallel Rays of Light: H. G. KELBS, University of Pennsylvania.

The *Drosophila* were placed in a tube 8 inches long and about 1½ inches in diameter. When placed in the light with the axis of the tube parallel with the rays no characteristic reaction could be observed. When the axis of the tube was tilted to an angle of about 45 degrees to that of the rays the flies at once showed their characteristic orientation. When, however, the ommatidia forming the central mass of the eye were painted over, the flies no longer reacted in the normal way when the axis of the tube was placed at the 45-degree angle, but would do so when it was placed parallel to the rays of light.

The following communication from a member of the society was received by the secretary too late for presentation at the Princeton meeting:

A Peculiar Structure in the Embryo of the Honey Bee: JAS. A. NELSON, U. S. Department of Agriculture.

In embryos from fertilized eggs of the honey bee, at the time when the germ layers are forming, but before the lateral folds have begun to unite, a small lenticular mass appears on the dorsal side of the egg, close to the cephalic pole. Its outer surface is almost plane, its inner strongly convex and studded with numerous delicate processes which join with the protoplasmic meshwork of the interior of the egg. This mass, which will be termed provisionally the cephalo-dorsal disk, appears to be a syncytium, composed of rather clear and vacuolated cytoplasm, within the inner half of which numerous nuclei are embedded. It lies at the surface of the egg and is continuous at its edges with the surrounding blastoderm. This structure was first noticed in 1904 by O. Dickel, who called it the "yolk plug." Dickel identified the point in the blastoderm where it first appeared as the blastopore, described the disk as formed by the migration of yolk cells to this point, and sought to connect it with the rudiments of the mesenteron, in an endeavor to interpret the process as gastrulation. A study of the antero-dorsal disk in sections of eggs of various ages shows: (1) that the so-called yolk plug does not arise from yolk cells, but from the blastoderm of the dorsal side of the egg by a cephalad migration of its cells and their aggregation at this point; (2) that at no time has the cephalo-dorsal disk any connection with the rudiments of the mid-intestine; (3) that during the stages immediately following the formation of the germ layers it becomes broken up into amoeboid cells which wander off into the yolk at the cephalic end of the embryo. It therefore appears to be a center of distribution for cells from the blastoderm to the yolk. Its homologies are obscure, although Hirschler (1908) has described a somewhat similar structure which he called the "dorsal organ," in the egg of the chrysomelid beetle *Donacia*. It is also interesting to note that the cephalo-dorsal disk has, in its position, time of appearance and structure a very close resemblance to the cell mass described by Petrunkevitch in the drone egg as derived from the polar bodies and later forming the male sex cells.

The following exhibits were made during the meeting of the society:

An Early Human Cranium: H. H. WILDER, Smith College.

Microscopical Preparations of Epithelium of Plathelminths: R. T. YOUNG, University of North Dakota.

*Microscopical Preparations to Show Amitosis in the Testis of *Tænia serrata*:* R. T. YOUNG, University of North Dakota.

JOHN H. GEROULD,
Secretary

DARTMOUTH COLLEGE

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS

THE fourth annual meeting of the American Institute of Chemical Engineers was held in Washington, D. C., December 20-23.

The reports of the various officers for the year were read, and a very gratifying growth in membership was shown. New officers for the year were elected as follows:

President—Dr. L. H. Baekeland. *Second Vice-president*—Dr. T. B. Wagner. *Third Vice-president*—Professor M. C. Whitaker; the first vice-president being Dr. Eugene Haanel. *Treasurer*—Dr. F. W. Frerichs. *Secretary*—Dr. John C. Olsen. *Auditor*—Mr. G. W. Thompson. *Directors*—Messrs. A. C. Langmuir, H. S. Miner and A. Bement.

The following papers were read at the Wednesday morning session:

"The Hardening of Plasters and Cements and a Simple Chronographic Apparatus for Recording Set," Dr. Chas. F. McKenna. A very ingenious as well as simple instrument for measuring and recording this important property of cements was shown and explained by Dr. McKenna.

"Advances in Testing Explosives," Clarence Hall.

"Distribution of Power in Portland Cement Manufacture," Richard K. Meade.

"Problems in the Manufacture of C.P. Acids," J. T. Baker.

"Combustion of Pulverized Coal," L. S. Hughes.

"Manufacture of Gelatin," Ludwig Thiele.

During the afternoon the institute visited the Bureau of Standards and inspected the standardization of weights and measures, adjustment of pyrometers, thermometers, pressure gauges and similar instruments, as well as the liquid air apparatus. Every one was impressed by the very excellent work being done by this important government bureau.

In the evening the retiring president, Dr. F. W. Frerichs, presented three papers illustrating the solution of problems in chemical engineering practise as follows: "Manufacture of Chloroform from Alcohol," "Construction of Laboratory Apparatus," "Manufacture and Testing of Shipping Cylinders for Liquid Ammonia." The paper on the "Manufacture of Chloroform from Alcohol" was especially interesting, as it showed that by the use of denatured, duty-free alcohol, chloroform could be manufactured from alcohol under present conditions and sold at a profit. The paper on "Manufacture and Testing of Shipping Cylinders for Liquid Ammonia Gas" was supplemented by the paper on "Manufacture and Testing of Carbonic Acid Cylinders," by John C. Minor, Jr. By means of lantern slides the method of testing cylinders was shown, as well as the results of exploding such cylinders under fixed conditions.

On Thursday, the institute visited the United States naval proving grounds at Indian Head, Md. This proved one of the most interesting excursions of the meeting. Four shots were fired from a twelve-inch gun. The method of loading, testing the pressure developed in the gun and velocity of the bullet were shown and inspected with the greatest of interest.

The plants for contact sulphuric acid, nitric acid, the manufacture of ether, nitration of cellulose, powder presses, recovery drying, as well as the testing of the raw materials and finished product were inspected with the greatest of interest.

In the evening a subscription dinner was held at the New Willard Hotel. Addresses were made by Patent Commissioner Moore, Dr. Harvey W. Wiley and Admiral N. C. Twining.

On Friday morning the institute listened to a number of very able speakers on the United States patent system. A symposium had been arranged for the purpose of bringing out defects in the present system and recommendation of the remedies to be applied. The following papers had been prepared and were presented:

"The United States Patent Office," E. B. Moore, Patent Commissioner, U. S. Patent Office.

"Protection of Inventions by Patents. Existing Defects and Remedies Therefor," Walter D. Edmonds, of Edmonds & Peck.

"The United States Patent System," R. N. Kenyon, of Kenyon and Kenyon.

It was the consensus of opinion that the present methods for granting of patents in use at the

United States Patent Office are better than any in use by any government in the world. The deplorable condition at the Patent Office on account of congestion and overcrowding due to the failure of the congress to provide suitable quarters for this most important government office, was brought out not only in the papers, but in the visit to the Patent Office during the afternoon. This condition prevails in spite of the fact that the patent bureau has been operated with such economy that a surplus of seven million dollars has accrued during its operation from excess of income from patent fees over expenditures.

It was also brought out that the most serious defects in our present patent system are met by the inventor after his patent has been granted. Intolerable delays occur, and enormous expense is involved in patent litigation, so that in numerous cases the patentee who does not have the strongest financial backing is defrauded of his rights by wealthy and powerful corporations. The remedy suggested for this condition of affairs consists in the establishment of a patent court in which all patent cases will be held, and also the hearing of all testimony in such cases in open court instead of before a referee.

On Friday afternoon the educational discussion which has been carried on at various meetings of the institute was continued, and the committee on education was requested to formulate the opinion of the institute on this important question and transmit copies of same to the universities and technical schools in the United States giving chemical engineering education.

On Friday evening, a paper was read by Mr. F. G. Wheeler on the "Adaptation of the Centrifugal Pump to Chemical Service." A complete discussion of the theories of the pump and all designs and makes with their behavior under operating conditions was given. The pump was illustrated with numerous lantern slides giving views of the pumps discussed.

A number of members of the institute visited on Saturday the steel plant at Sparrows Point, Baltimore, and the cement plant of the Tidewater Portland Cement Co.

The attendance at the meeting was excellent, and general satisfaction expressed at the results accomplished.

IN March, 1911, Mr. Andrew Carnegie transferred to the trustees \$1,000,000 of five per cent. bonds of the United States Steel Corporation, the first instalment of the gift of \$5,000,000 offered in his letter of March 31, 1908.

This amount brings the funds at present in the hands of the trustees to a total of somewhat over twelve millions of dollars, of which eleven millions are invested in five per cent. bonds of the United States Steel Corporation and approximately one million, the result of accumulated surplus, is invested in other securities, purchased upon the approval of the finance committee and listed in the treasurer's report.

The total income at the disposal of the trustees for the fiscal year just ended amounted, as shown in the treasurer's report, to \$590,449.54.

The total expenditures of the trustees were distributed as follows:

Retiring allowances and pensions in accepted institutions—		
Teachers	\$341,899.16	
Widows	46,720.17	\$388,619.33
Retiring allowances and pensions to individuals—		
Teachers	\$122,215.10	
Widows	16,044.57	138,259.67
Salaries, publication, rent, etc.		53,564.21
Total expenditure		\$580,443.21

¹RECEIVED intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹Extracts from the sixth annual report of the president, Dr. Henry S. Pritchett.

In the report of last year I sought to call the attention of the trustees and of teachers in colleges and universities to the specific things that a retiring allowance system could do, and also to the limitations of such a system. The experience of the past year prompts me to refer again to these limitations, and to the extreme difficulty of making exceptions to the rules framed for administering the income of the foundation.

The specific things that the system of retiring allowances maintained by the foundation offers to the college teacher are three in number: (1) a fair retiring allowance after sixty-five years of age; (2) a disability allowance after twenty-five years of service as a professor, in case of a failure in health so complete as to unfit him for his work as a teacher; (3) the payment to the widow of a professor who has had twenty-five years of service, of a pension equal to one half of the allowance he would have been entitled to at sixty-five. I am inclined to think that the protection of the wife and family thus provided is the most valuable and, in many cases, the most highly appreciated service that the system of retiring allowances can render. These benefits accrue to the teacher under specific rules, according to which he himself and the officers of his college may know, quite as well as the officers of the foundation, whether he has had a service which makes him or his widow eligible under these rules.

The executive committee of the foundation has spent much time over cases which, falling outside of these specific provisions, are urged upon their attention by college authorities, by friends of those desiring relief and by the applicants themselves.

These requests are justified in part by the action of the trustees in giving to the executive committee permission to extend the benefits of the retiring allowance to certain exceptional cases—notably to men who de-

sire to devote themselves to research, and to college executives who have rendered noteworthy service. As a matter of fact, the executive committee has never made use of this authority granted by the trustees, and I am convinced that the difficulties of making such exceptions are so great that the committee will find it necessary to abide wholly by the fixed rules.

The idea of giving, by the granting of a pension, opportunity to men of proved ability to devote their whole time to research was a very attractive one to the trustees and officers of the foundation at its inception. It was felt that a by-product of the retiring allowance system which would be of great value might here be obtained.

Unfortunately, experience has not justified this hope. This is due to a number of causes: partly to the fact that there are yet few men in the colleges and universities engaged in advanced research; partly to the tendencies of the colleges themselves and to the qualities inherent in human nature. Experience shows that under the encouragement offered by this action of the trustees, a considerable number of teachers who had done nothing in research hitherto suddenly discovered that they had a mission in that direction. Further, the college authorities were ready in many cases to recommend as qualified for research professors whom they had found ineffective as teachers. Finally, in the cases of men genuinely interested in research and prepared to undertake it effectively, there is some question whether such provision by the foundation would not weaken the sense of responsibility among the colleges toward research and those undertaking it.

The experience of the foundation in considering special cases among "those whose twenty-five years of service include noteworthy presidential or other administrative work in a college or university" has

brought out still more strongly the difficulty of making exceptions. Every college president considers his case an exception, and all of his friends consider the record of his services as noteworthy. A board of trustees dismissing a college president to make way for a new man will in most cases certify in the highest terms to the extraordinary character of the departing president. It is very true that most such men have given to their work a high order of devotion and of disinterested service; no college presidents are more deserving than some of those that are forced out by their boards of trustees. On the other hand, it is practically impossible to compare the records of such men and single out a few for recognition without doing great injustice to others. The hardships of college presidents—aside from those that arise from their own failings—come from the defects and the crudeness of our comparatively young educational system. Part of these are due to an over-production of colleges and consequently of college presidents. Compensation for such inequalities can not be brought about by the action of a pension agency. The cure must come from a gradual improvement in our educational organization, and a more enlightened attitude on the part of the public and of college trustees toward those who are responsible for educational administration. It is as difficult to select the especially deserving president or dean as to select the special teacher whose work has been of noteworthy character. The effect of such legislation by the trustees has been to arouse hopes on the part of many presidents that they might in case of such an emergency as dismissal from office be considered in a special class entitled to the receipt of a retiring allowance. The experience of the past five years shows that

the administration of such a rule is impracticable.²

Other requests and recommendations that come to the executive committee cover almost all possible variations from the rules. The most common are those in which the teacher has served for a shorter period than twenty-five years and suddenly breaks down in health or dies leaving a helpless family. These are indeed the most pathetic cases that one can meet. Here again, however, a little reflection will show how impossible it is to go outside of the established rules without embarking upon an entirely new pension system. Again, it is impossible for a pension system to take care of individuals who neglect to use reasonable prudence in the affairs of life. The teacher's salary is often pitifully small. To provide even modest insurance against the death of the breadwinner seems often too great a burden to add to the already heavy load. Oftentimes, too, the men who are thus cut down early are those who have thrown themselves into the service of education with a splendid enthusiasm, and sometimes with a reckless disregard of their own health and of the claims of their families.

²At the meeting of the trustees, November 15, 1911, the action which empowered the executive committee to make exceptions in the cases of "those whose twenty-five years of service include noteworthy presidential or other administrative work in a college or university" was rescinded. No person has ever been retired under this authority. The only exceptions to the rules now recognized by the trustees are in the cases of men of proved ability in research, who would in the judgment of the trustees be able to render unusual service to science if free from teaching duties. Such cases will be extremely rare. Experience shows that research in general flourishes in the contact of investigator and student. No retirement has as yet been made under this provision. Such action would mean in any case the highest recognition the trustees could render of their appreciation of ability already demonstrated and of their expectation of still higher achievement to follow.

ilies. There should be somewhere some provision for such cases. But it is clear that the just remedy for such exceptional misfortune does not lie in a disregard, on the part of those administering the present pension system, of the rules established for the welfare of all. Some, at least, of these cases should be met by the colleges.

The presence of the altruistic spirit among college teachers is strong, but perhaps no stronger than among other classes of educated men. As in every calling, a large number of those in the profession of the teacher are drawn to it by bread and butter reasons. The offering of a pension can not fail in some cases to minister to the selfish side of human nature. There will always be some who, when they find themselves in possession of a given advantage, whether that take the form of a benefit in the hand or one to be acquired in the future, will trade upon the possession or the prospect of that benefit. Under the present rules there will be a certain number of teachers who will count the years and the days until the coming of the minimum age which enables them to resign the duties that they now perform in a perfunctory and machine-like way. There are still other men facing responsibilities and difficulties in administrative places or in teaching who would gladly use the method of the pension to escape from the perplexities and responsibilities of their positions. Presidents are prepared to prove to the foundation, even when they are turned out of office by the trustees for alleged incompetence, that they are entitled to a pension on the ground of extraordinarily meritorious service. Too many teachers, too, think that they are entitled to consideration of a special sort by reason of their particular and unusual service. All this arises out of the qualities of human nature, and out of

the qualities of some of the men who to-day make up the faculties of our colleges. On the whole, the number of those whose selfishness is directly touched by such an opportunity is small, as small perhaps as one ought to expect, and in the long run much of this spirit will disappear as the teachers themselves become accustomed to a system of pensions. In time teachers will realize that it is for their own interest and in the direction of their own happiness to continue to work as long as they are really fit and able to serve. The late William T. Harris always insisted that a college professor was at his best between the ages of sixty-five and seventy, and he strongly urged the trustees of the Carnegie Foundation at the inception of the trust not to make the minimum retiring age lower than seventy. Mr. Harris's argument was a partial one, but it had some truth in it. There are many teachers who are at their ripest and at their best between sixty-five and seventy-five, and such men ought, of course, to remain in their profession. In the long run it will be found that they will do so, although for a few years the idea of the pension will induce some men to surrender work at an earlier age than they ought. It is impossible to offer to men an advantage such as that which flows from a pension system of any sort without arousing in some minds the question, How can I get the most out of it? The number of such individuals among college teachers, however, is small, and will, unquestionably, become smaller as the standards of college life rise.

Nor can one shut one's eyes to the fact that the colleges themselves may, by reason of the pensions of the foundation, neglect their own duty in taking care of their old teachers. This also, in my judgment, is a temporary and passing phase of the situation. The officers of the foundation have

done all in their power to make it clear to the colleges that the funds at their command, and likely in the future to be at their command, could care for only a limited number of colleges. Nevertheless, in spite of this effort, it has been tacitly assumed by many colleges, and generally by those of the lowest standards in scholarship, that any obligation on their part to care for their old teachers vanished with the inauguration of the foundation.

Notwithstanding the disadvantages, however, that must occur in the administration of any such system of these pensions, it seems clear that the advantages that have resulted from the conferring of pensions have greatly outweighed the disadvantages, and that, furthermore, the advantages on the whole seem likely to become stronger with time, while the disadvantages tend to diminish. The value of a pension system depends not only on those who administer it, but no less on the spirit and *morale* of those who are to participate in its benefits. The dangers of a non-contributory system lie mainly in those universal dangers that come from human weakness and human selfishness.

It is, to my thinking, a fair question whether college pensions ought not, like other pensions, to carry a contributory feature. No one can be more sensible than I of the tremendous demands made upon the meager salaries of the American college teachers, and yet notwithstanding this, it is impossible to remove the college teacher from those social and moral influences that affect all men. The experience of the world seems to make clear the fact that on the whole a contributory form of pension is likely to be most just and least harmful.

The sacrifice of the individual to which I have referred is directly connected with the question, "What obligations rest upon a college to care for those who have grown

old or have broken down in its service?" This question is rendered more urgent by the establishment of the Carnegie Foundation. In every report of the foundation attention has been called to the fact that the income that it is likely to have can provide at most for only a small minority of the college teachers of the country. All that the trustees can hope to do is to establish the principle of a generous and fair retiring allowance system as a part of the régime of higher education in the United States. The question, What is the duty of the college in this matter? still remains, even to a considerable extent, in the accepted institutions. In these institutions the main burden of pensions is carried by the foundation, but the obligation of these institutions to care for those who have served them well, and who are not eligible to retirement under the foundation, still remains.

The question as to the duty of the college is, of course, only part of a larger question that all organizations in the social, educational and industrial circles of our country are now facing. The relation of a pension provision to efficiency and the obligation of a corporation to its servants is being discussed to-day from every point of view. The college must face this question just as other corporations are facing it. One does not need to be an extreme individualist to realize that the individual is too often sacrificed to the service of the corporation. Perhaps in no form of organization is this more often true than in the colleges. We need constantly to be reminded that colleges, as other human organizations, were made for men; men were not made for colleges. The obligation rests upon every organization in the social order to deal fairly with the question, how far it is accepting the sacrifice of the individual in order to promote the organization, or the

cause that the organization is supposed to serve.

This question presents itself in a very acute form in our colleges. A large proportion of the colleges overwork their teachers in the effort to take more students or to teach more subjects. College loyalty is constantly invoked to justify the placing of an additional burden on the shoulders of an already overworked teacher, and college loyalty looks less frequently to thoroughness and quality than size. Under these circumstances, is there not a clear duty resting upon the college authorities to use part of the income in their hands in the support of those who grow old or break down under this régime?

There is a widespread tradition that corporations have no souls. But of all soulless corporations, the colleges probably have the smallest compassion so far as the question of dealing with their old servants is concerned. Few business corporations would be as heartless toward an old officer as a very large proportion of American colleges are. In the most of these, a worn-out president, an aged professor or a teacher struck down by illness is simply turned out to shift as best he may. In fact, the college trustee has been surrounded by such influences that he invokes his responsibility as a trustee to justify the plea that under no circumstances can he use any of the income of the college, whether from endowment or tuition, to care for those who break down in the college service. It is exactly here that the question of the duty of the college arises. Has any corporation the right to use the service of individual men of high devotion and intelligence up to the end of their working ability, without assuming some responsibility for their future? Is it to the interest of society, of human progress, of education itself, that any corporation should divest itself of such

responsibility? This is a question that all organizations of society must face, and the college, to say the least, can no more escape it than can the industrial organizations. The colleges have undeniably failed in the ethical leadership that might have been expected in these matters. It is impossible, however, to believe that they will not rise to the moral standard now set by the business world.

The public perhaps scarcely realizes how indifferent the colleges have been in the past to this question. The correspondence of the foundation during the last five years throws an interesting light on this whole matter, and brings out in the sharpest relief the fact that the very idea that the college has a moral obligation to its worn-out professors has not yet presented itself to most college officers and trustees as one of the things with which they are to reckon.

Communications like the following are typical. The president of a board of trustees writes that Professor A., having served the college faithfully for twenty years and having broken down absolutely in health, is compelled to stop work altogether. He is without means and has a family. It is plain that he is not eligible, under the rules, to a pension from the Carnegie Foundation, but, writes the president of the board, will not the foundation waive its rules in this case in view of the high service and pathetic situation of the teacher and care for this excellent man? For, he adds, "Of course the college can do nothing." And yet this college had an income that is generous when compared with those of most colleges. It had spent a large sum on an athletic field the previous year, and it was spending at that time more money on advertising than would be necessary to pay such a pension several times over, and this in spite of the fact that it had more students than it could care for decently. The

college trustee needs to get a clearer perspective as to his obligations and those of his college.

An institution of large income and high standing applied to the Carnegie Foundation for the retirement of a dean, a man **seventy** years old, who had rendered to his institution a long and distinguished service, and who stood high in the affections of the old students. The retiring allowance was voted, in view of the long service and scholarly character of this man, and it only became known months later that the trustees had arranged, in case the pension were not granted, to dismiss this faithful servant on the ground of advanced age.

The reason for this lack on the part of college trustees of that sense of responsibility for the old servant which is so striking a feature of modern civilization does not lie in any extraordinary callousness on the part of college trustees. It arises simply out of the conditions of our American colleges as related to our educational problems. The college trustee has been so trained that he looks upon any such expenditure as wholly outside of those purposes for which the college can spend its money. Not infrequently a trustee puts his hand into his own pocket to relieve (at least temporarily) the situation of a broken-down teacher, when his conscience would not allow him to spend a cent of the college money for such a purpose. Exactly the same thing happens in churches. An old and worn-out pastor is turned out to spend the remnant of his days in abject poverty—helped out now and then by casual gifts or meagre pensions, while the officers of the congregation would feel hurt at any suggestion that they had acted ungenerously. Yet it seldom occurs to them that the affectionate support of an old and faithful servant through his declining years would probably be the most christian act that the

congregation could perform. This whole matter has not yet been brought within the perspective of college trustees. The time has come when this must be done. It is probably true that only a few colleges are in a position to maintain a satisfactory and generous pension system for all their teachers, but no college that is prepared to educate youth with fair efficiency is exempt from the obligation to make modest provision for those who have served it long and faithfully and who have come to the limit of their working capacity. This is simply one of the ordinary obligations of human society which all corporations in a civilized christian community must acknowledge. It is worth more to the education of young men to provide a decent support for an old teacher than to build athletic fields or even to add a new dormitory. On the other hand, a broken but deserving teacher, turned out to shift for his remaining years as best he may, is a spectacle which does more harm to the cause of education than can be atoned for by large classes of undergraduates, or a graduate school conducted at the expense of the legitimate work of the college. In a word, the obligation to care for the old servant is one of the fundamental obligations of human society, and the college can not evade it without incurring the sort of penalty which follows the evasion of all obligations. According to its ability, every college, however modest, must meet this obligation. The board of trustees that turns out an aged and faithful teacher with the phrase, "Of course the college can do nothing," simply does not appreciate that such an act is a blow at the integrity of the educational cause that they are supposed to serve, and that it is better for the college itself to make its economies elsewhere than in the evasion of the old-fashioned christian obligation to care for those who have borne the burden and heat

of the long day. The appreciation of this fact on the part of the great number of college trustees has hardly begun. It will be a matter of slow education, but it will come, and in just such proportion as standards of honesty, of sincerity and of human brotherhood improve in the colleges themselves.

And it is fairly safe to say, from past experience, that progress in these moral standards will follow close upon progress in scholarly standards. Educational righteousness will not be divorced from other forms of right living. The college which holds up sincere and fair scholarly standards will in the long run be the college that will bring to its service trustees who can face intelligently all their obligations, whether they be to the college as a whole or to the individual student or teacher.

In the present status of higher education in America there are many conditions that make it easy for college trustees to disregard the obligation to the individual in the face of numerous demands in other directions. In almost every state of the union there are more colleges in name than the country needs or can afford. They have been started without much regard to the ultimate educational demands. Many of them have existed by doing the work of high schools, and now that the high school system of most states is being rapidly developed, many of these institutions, founded in an educational enthusiasm and having neither the means nor the facilities for doing college work, have a hard struggle for existence. Denominational, state and local rivalries have done much to swell this list of weak and often superfluous colleges. In many cases their existence makes impossible that of good high schools which would far better serve the educational interests of the community.

For example, in Nebraska, which had a

population in 1910 of 1,192,214, there are thirteen colleges and universities, all in the fertile and populous southeastern quarter. One of these thirteen institutions is the well-supported and accessibly located state university, another is a university conducted by the Jesuit Fathers, and a third is a privately endowed institution. Each of the remaining ten colleges was founded by a protestant denomination, is controlled by it, and appeals to the denominational constituency for support. One of these colleges gives in its catalogue no means of estimating the number of its college students. The other nine have a total college enrollment of 841, or an average of 93 college students each. The total enrollment of all of the departments of these institutions, apart from summer schools, is 3,051, or an average of 340 each. It thus appears that these colleges, founded in days of pioneer enthusiasm or of boom prospects, and maintained by efforts of denominations and the sacrifices of individuals, are chiefly engaged in preparatory, music and business school work, rather than in college education. To reduce these ten struggling colleges to two or three would relieve many conscientious people from severe financial pressure, and would greatly improve the level of higher education in Nebraska.

Similarly, in Pennsylvania, there were, at last reports, fifty-one institutions calling themselves universities or colleges. A baker's dozen of these are wholly secondary schools, in no way entitled to the name of college. Three universities in Pennsylvania can perhaps make that title good. There is one state college. There are also six worthy non-sectarian colleges. The remaining twenty-eight institutions are denominational schools and colleges—six of the Roman Catholic church, five of the Lutheran and five of the Presbyterian denominations. Three other denominations

have two colleges each and six others have one each. At least half of these denominational institutions are small, struggling and of low educational standards. One of the Presbyterian "colleges," for instance, is made up of 164 preparatory and 44 college students. One of the Lutheran "universities" is composed of 35 preparatory, 48 collegiate, 12 professional and 17 *graduate* students, 15 of the latter being non-resident. Assuming that the denominations can make real contributions to higher education, such multiplication as this is surely unjustifiable. Its effect is to reduce all education to a lower level and to depress all betterment of the teacher's place.

When an institution calling itself a college hires its professors by the month, and pays such salaries as only youths just out of college can accept, it is not to be expected that a high sense of obligation will characterize its trustees. In the gradual process of the country's growth such institutions will either disappear or find their true place, many of them as secondary schools. But, meanwhile, it is not in these institutions that one must expect a just sense of appreciation of a professor's service. It is in the stronger colleges, whether small or large, that one must expect the beginning of the movement for a just recognition of the obligation that the college owes to an old and faithful servant.

Quite naturally, the creation of the Carnegie Foundation conveyed to many college boards the impression that the establishment of such an agency lifted at once from the shoulders of college authorities all obligation to care for their worn-out or disabled teachers. The very opposite is the fact. The creation of the Carnegie Foundation makes clear and emphasizes the obligation of educational organizations to deal justly, thoughtfully and generously with those who have given a life's service

to education. The very purpose of the fund is to arouse in college authorities an appreciation of this obligation. The trustees of the foundation can provide retiring allowances for only a small fraction of the college teachers of America. The duty of the individual college in this matter still remains, and is but the greater now that the principle has been made clear.
